19. ABSTRACT (Continue on reverse if necessary and identify by block number) Description of the geology of the Gallipolis Locks and Dam site and a discussion of how the							
existing foundation conditions is the purpose of this report. The Gallipolis Locks and Dam							
is on the Ohio River at mile 279.2 near the town of Gallipolis, Ohio. Geologically, the							
area lies in the Kanawha section of the Appalachian Plateau Physiographic Province. The							
Pennsylvanian Age Rocks are mostly sandstones, shales, claystones, coals and silistones.							
The principal features of the project are two adjacent, parallel lock chambers constructed							
as conventional concrete gravity-wall structures founded on rock. The report describes in							
detail the procedures used to establish foundation grades, and to excavate and treat the							
foundations. Pertinent correspondence relating to foundation conditions along with typical							
foundation treatment photographs is included. Geologic cross sections, foundation							
treatment profiles and boring logs are part of this report.

SECTION I

INTRODUCTION

1.01 Purpose of Report

The purpose of the this report is to insure the preservation, of the complete records of the foundation conditions encountered during construction and the methods used to adapt structures to these conditions.

1.02 Scope

The scope of this report covers the investigations, observations and treatments that were relative to establishing sound foundations for all structures erected for the Gallipolis Lock Replacement Project under contract DACW-69-88-C-0001.

1.03 Construction Authority

The authority for construction of Gallipolis Locks Replacement was granted under Water Resources act of 1986 (PL-99-662).

1.04 Project Location

The project is located in the Middle Ohio Valley at Ohio River Marker 279.2. This indicates that the project is 279.2 miles below or downstream of Pittsburgh Pennsylvania. A closer Monument Marker is the Kanawha River. The Project area is fourteen miles below the mouth of the Kanawha River. The new Locks are located on the West Virginia side of the Ohio River, in a canal. The existing locks are adjacent and parallel to that position.

(For a location map see Section XIV Exhibit #1.)

1.05 Project Description

The description of the Locks is as follows: Two adjacent, parallel lock chambers located in a canal directly east of the existing locks. The lock walls are a conventional concrete gravity-wall structure founded on rock. The Main Lock Chamber has a clear dimension of 100 x 1,200 feet and the Auxiliary Chamber 100 x 600 feet. The Main Lock location is west of the Auxiliary Lock. The Upper Approach wall is 1,200 feet long, measured from the upstream nose of the Middle Wall. The Lower Approach Wall is 1,000 feet in length, measured from the downstream nose of the Middle Wall. The Lower Approach Wall is founded on sheet pile cells, filled with concrete. The Middle Wall is 1,940 feet in length. The Land Wall is 1,292 feet in length. The upstream and downstream entrances use structural steel Miter Gates with hydraulically operated Gate machinery. A double leaf, vertical lift, submersible gate, electrically operated is located upstream from the Miter gate. The elevation at the top of the Lock Walls is 560 feet above sea level.

(For a Site Plan See Section XIV Exhibit #2.)

1.06 Project History

The original or existing Gallipolis Locks and Dam were completed in 1937. It was the last project in the original system. The Ohio River, modernization program began in the late 1950's. Upon completion, it replaced three older locks on the Ohio River and three on the Kanawha River. The Navigational pool extends 41.7 miles up the Ohio River and 31.4 miles up the Kanawha River. Inspections conducted in the 1970's found the navigational locks to be in fair condition. The concrete walls are progressively deteriorating misaligments of some wall monoliths were observed. Due to the increased wear resulting from frequent operation of the lock chambers, some equipment and gates are estimated to need replacement in ten years. Rehabilitation of the existing structure was economically feasible. However, due to the increasing size of the barge tows, a new locking structure was decided upon. The new structure has a 1,200 foot Main Chamber and a 600 foot Auxiliary Chamber. The locks are located in a bypass canal. The dam will be rehabilitated upon completion of the locks. This was considered the best plan. because it allowed for the passing of traffic in a safe and efficient manner and for improving overall navigation performance. Construction of the new locks began on 22 November 1987 and was beneficial occupancy on the 23 January 1993.

1.07 Contractor

The prime contractor for the construction of Gallipolis Locks was a consortium of four companies. At the start of construction, the sponsor was S.J. Groves and Sons. The other partners were: Guy F. Atkinson Construction Company, Dillingham Construction Company and Harbert International. The consortium did business as GLR, (Gallipolis Lock Replacement) P.O. box 1267, 10000 Highway 55 West Minneapolis Minnesota 55440. On 28 October 1989, Guy F. Atkinson Construction Company assumed the sponsorship of the project. S. J. Groves and Sons remained as a partner. The contract was awarded on 21 November 1987.

(For a list of composite contractor personal see Section XI, page A.)

(For a list of subcontractors see Section XI, page B.)

1.08 Contract Supervision

This contract was performed under a Contractor Quality Control Program. The Quality Assurance Program was conducted through a Government Resident's Office located at the construction site. This office was administered by a resident engineer acting as legal representative of the contracting officer (Col. Robert D. Brown) District Engineer. Due to the work load, the Resident Engineer's Staff varied during the construction program.

(For a composite list of Government Personal see Section XI, page C.)

SECTION II

FOUNDATION EXPLORATION

2.01 Investigation Prior to Construction

Investigation prior to construction began in 1964 and ended with the awarding of the present contract. These investigations were performed to evaluate the foundation characteristics and to determine the amounts and types of construction material present at the site.

2.02 Soil Investigation

The soil investigation during these programs consisted of 149, two inch, split spoon, standard penetration test samples. Twenty-two samples were either four inch or six inch diameter sample tubes and were sampled using a cable tool drill. Nine undisturbed samples were taken by fixed piston. All soil samples were visually classified in the field. Selected samples of both disturbed and undisturbed types from the excavation site were sent to the ORDL (Ohio River Division Laboratories) for testing. The test consisted of the following: Visual classification, Water content, Atterberg Limits, Specific Gravity, Q and R. Triaxial and S. Direct Shear.

2.03 Rock Investigation

The bedrock investigation in the area of the proposed structures was accomplished by drilling four inch and six inch diameter cores. The drilling was done on 250 foot centers along the wall alignment. NX size cores were taken and used to supplement the data from the larger diameter core holes. The four foundation rock types found are: Sandstone, Siltstone, Shale, and Claystone. Sandstone and siltstone are foundation mediums in the downstream area. In

the Auxiliary Chamber, North of the Miter Gate, the rock starts to transition into an interbedded Claystone and Shale. The Claystone and Shale serve as foundations for the upstream portion of the monoliths. Typical cores representing these four foundation rock types were shipped to ORDL (Ohio River District Laboratories) for testing. All samples were tested according to the United States Army Corps of Engineer's Rock Testing Handbook.

The following types of test were performed on samples of the four rock types: Direct Shear with Sliding Friction and with Deformation Readings, Unconfined Compression tests, Unit Weights, Moisture Content and Specific Gravity. Also Rock-on-Rock Sliding Friction tests and Grout-on-rock Bond Strength tests were performed. All rock samples were tested except for Indurated Clay. Indurated Clays were not used as a foundation medium.

(The detailed results from the above Rock and soil sample testing can be obtained from Design Memorandum NO.1, NO.2, NO.3 and Results of Direct and Cross-Bed Shear Testing of Rock cores, November 1984)

2.03.a Rock Test Results

<u>Problems</u>. Most of the problems associated with the rock testing program were related to either sample selection or the integrity of the indurated clay and claystone samples. Sample selection was complicated by the gradational nature of the siltstones and claystones and the indurated clays. The upstream portions of the lock structure are founded on a rock type classified as interbedded claystones and siltstones. While the claystones and siltstones are interbedded, they do not occur at consistent elevations from hole to hole. The individual beds appear to be in a constant state of gradational change or may exist as a series of "pods" or lenses. Due to the nature of these beds, there is no certainty that all the samples selected for an individual rock type are truly representative samples. This condition is mitigated somewhat by the fact that the claystones are obviously the weaker of the two interbedded rock types. Thus, the samples selected for testing from the interbedded materials were claystones.

Sample integrity was a problem for both the claystones and indurated clays. A large number of samples for the compression and shear tests were rendered unusable during transportation from the field and during transportation to the laboratory. Some samples were placed in PVC tubing and encased in plaster in order to reduce damage during shipment. While this

proved to be of benefit, some of the compression tests had to be corrected to account for sample lengths which were less than twice the sample diameter.

<u>Interpretation</u> of <u>Test Results</u>. It is recognized that the problems discussed above are indicative of the nature of the foundation materials. Problems such as these also indicate the need for conservative interpretation of test results since the samples are representative of the more competent portions of the foundation. As a result, the data from the testing was generally interpreted using statistical methods to identify a 90 percent lower-bound envelope. The lower bound represents an envelope which would lie below the linear regression line for nine out of ten testing programs in the same material. In some instances, the lower bound envelope was unreasonably conservative by virtue of the fact that little or no difference could be distinguished between the lower bound for the peak direct shear and the sliding friction tests. In these cases, which are identified by an asterisk in Table 1, a visually determined lower line of best fit was used for the interpretation. Since the design for a large portion of the project is controlled by the envelope for the interbedded material, additional testing is planned to confirm the design values for this material.

Allowable Bearing Pressures. The allowable bearing pressures exceeded the foundation pressures in all cases. The maximum foundation pressure for the lock structure is 20 KIPS or 138 psi. The minimum average unconfined compressive strength for any bed on which structures are founded is 1712 psi. (Table 1). Thus the bearing capacity, which is generally accepted to be equal to the unconfined compressive strength, exceeds the foundation pressure by a factor greater than 10. The allowable bearing pressure used in the design was 50 KIPS (347 psi), which provides a safety factor of slightly less than 5.

Indurated clays do not serve as the founding medium, for any structure. Their presence in the foundation at depths which exceed 5 feet was noted, and an analysis was performed to determine whether transmitted pressures were within allowable limits. The analysis (after Goodman 1980) showed that the transmitted pressure was less than 20 psi. Since the average unconfined compressive strength of the indurated clay is 185 psi, a safety factor in excess of 9 exists without taking into account the effect of the confining pressures to which the material is subjected.

The access road bridge will be founded on piles driven to rock, and each pile will sustain a 50-ton load. The sandstone which will be present at top of rock has an average unconfined compressive strength of 4820 psi. In order for the unit load to equal this strength, a pile area of 20.7 square inches will be required. This type of approach disregards the confinement of the overlying

materials which will ad significantly to the capacity of the foundation. For this reason, the selected pile will have an end area of approximately 20 square inches. Pile caps may be used to increase the end area, depending on the strength required for the steel piling.

TABLE 1

2.04 Investigation During Construction

During the construction, investigations that were preformed can be divided into visual and physical. The Visual investigation was the continuous observation of conditions that were exposed during excavation. These new conditions were then compared to the interpretations and conclusions derived from previous exploratory programs. These interpretations were then verified or the design revised to fit the existing conditions. Inspections were conducted by personnel from the District and Division Offices. The results of these inspections are included under their respective headings, discussed later in this report.

Physical foundation investigation was confined to exploratory borings. Under Division 2 of the specifications the contractor (GLR) was required to drill four inch cores before excavation. The approximate locations of the exploratory drill holes are shown on the drawings. The following are the quantities and locations of the subsurface program. There are 18 borings in the Lower Approach Wall, 42 borings in the Upper Approach Wall, 94 borings in the River Wall, 87 borings in the Middle Wall, 50 borings in the Land wall, 5 borings in the Inlet Structure, 5 borings in the Outlet Structure, 7 borings in the Land Culvert, 1 borings in the Middle Culvert. The information derived from these borings was used to supplement preconstruction exploratory information. The combined information was then used to either to confirm or used to establish new founding elevations for the monolith structures.

(For locations and detailed logs of these borings see book #3.)

SECTION III

GEOLOGY

3.01 Physiography and Topography

The Gallipolis Project area is located in the Ohio River Basin. The Ohio River Basin is part of the Kanawha Section of the Appalachian Plateau Physiographic Province. The present landscape evolved when an area of little or no relief was uplifted. The uplifted area was deeply dissected by subsequent down cutting of rejuvenated streams. The surface maybe described as an elevated, somewhat rolling plain. The rolling plain was dissected by the destructive actions of running water. This developed an intricate system of hills and valleys. The degree of the dissection and the difference in the underlying strata has resulted in a variety of topography. The topography ranges from slightly rolling plateaus intersected by narrow, steep-walled valleys to the Appalachian Plateau. The App.alachian Plateau has been dissected into a series of flat topped hills and ridges separated by narrow valleys. While the valleys have grown wider, the hills have become sharply crested. The streams now assume meandering courses across the valley floors.

The drainage patterns established by these post-uplift streams have been extensively modified by glaciation. Although the glaciers did not enter the project area, they did block the northward flow of the primary streams of the drainage basin. The drainage system in the project area today is dendritic. The Ohio River is the primary stream in the present drainage system. The present drainage system was formed when the old channel segments were connected with new segments. These segments were connected by cutting across low points in the drainage divides. The Ohio River has subsequently developed into a mature stream. The flood plain at the project site is approximately one mile wide and is flanked by hills approximately 300 feet high. Elevations in the area of the project (Mason County) range from 1070 feet above sea level to the Ohio River normal pool elevations (515 downstream and 538 upstream). The Ohio River drainage basin consists of 20,560 square miles.

3.02 Seismicity

The project is located in the seismotectonic region known as the Central Stable Region. The largest known earthquake in this region since 1820 occurred in Attica, New York in 1929. The attica event has been characterized as an VIII Modified Mercalli, but recent evaluations assigned a VII to this event.

The Gallipolis project lies in an area characterized by low seismicity. Historically, within this tectonic region, there have been four earthquakes with Modified Mercalli Intensities of VI (VI MM) and no known events greater than VI MM since 1776. The return period for a VI event at Gallipolis is in excess of 200 years and the probability of occurrence within a 50 year period is 20 percent. The return period for an VIII event at the project is more than 5000 years. The probability of occurrence in a 50 year period is 1 percent. The acceleration value for Gallipolis Locks Replacement is .05G. This was considered reasonable and unlikely to be exceeded during the life of the project.

3.03 Description of Overburden

The overburden within the project area consists of deposits of alluvial sediments. The alluvial deposits consist of sediments of clay, silty clay, sandy clay, clean sand and sand with rock fragments. These sediments were partly derived from the sandstones and shales found upstream. Also found in these sediments are the remains of igneous and metamorphic rocks, referring to glacial origins. Some of the common types found were: Pink Granite, schist, quartz and pegmatitic rocks. The down cutting effect of area streams, combined with spring floods have eroded and transported these materials to place them at their present locations. Some of the smaller streams have intermixed these sediments to various degrees on the project. The average thickness of these sediments ranges from fifty to sixty feet.

3.04 Bedrock Stratigraphy

The Kanawha section of the Appalachian Plateau consists of sedimentary rocks of the upper Pennsylvanian to lower Permian age. Included in this period are the formations from the Conemaugh series.

Within the project area, the combined vertical extent of this series is about 570 feet. The Conemaugh series consists of several sandstone members. Many of the sandstones contain discontinuous shale lenses. These sandstones grade from coarse grained micaceous sandstones in the Southern end of the project, to fine grain siltstones and/or shales in the north of the project. The series is 450 feet to 600 feet thick and contains the sequence of strata from the lower Pittsburgh Sandstone to the lower Mahoning Sandstone. The Conemaugh is divided into 23 mapped members, but only four, The Connelsville Sandstone, The Clarksburg "Red Beds," The Morgantown Sandstone, and The Birmingham "Red Beds," are mapped at the project.

The Conemaugh, like other Pennsylvanian formations, is defined boundary wise by referencing it to coal beds. The Conemaugh contains little coal of commercial value in West Virginia. The series is sometimes referred to as the "lower barren measures." The sandstone members were possibly deposited in a broad delta and/or flood plain by streams transporting material from adjacent elevated land masses.

3.05 Bedrock Structures

The Appalachian Plateau Physiographic province contains 120 anticlines and an equal number of synclines. All have been mapped and described. Many are small or minor folds and of only local significance. Many of these anticlines and synclines are in the western part of the state of West Virginia. These features readily parallel the trend of the Allegheny Mountains. There are no significant structures due to these anticlines. Strata dip is E-W and strike is N-S. The two most significant structural features at the project site are: slicken - slides in the clay and claystone and some sedimentary structures. These sediment features are normal faults. Accompanying these are broken zones or zones of intense fracturing.

3.06 Economic Geology

The Conemaugh series has produced gas, oil, and coal. The coal producing beds of the Conemaugh series are: The Little Pittsburgh, The Little Clarksburg, Elk Lick, Harlem, Upper Bakerstown (Thomas), Brush Creek, and Mahoning. The Harlem, Little Pittsburgh, and Little Clarksburg have not been

mined in West Virginia. The coal beds of the Conemaugh Series are of little commercial value at this time.

The Connellsville, Morgantown, Saltsburg, Buffalo, and Mahoning sandstones have produced some oil and gas. In the state of West Virginia they are named Minshall, Murphy, Moundsville, First Cow Run, Little Dunkard, and Big Dunkard Sands respectively.

Some of the limestones are suitable for producing building stone, agricultural lime, Portland cement, and road materials. Several of the sandstones have been quarried for general building, ornamental stone and pulpstone.

3.07 Bedrock Weathering

The topography of the Ohio River basin at the project site is an example of differential weathering that accompanies valley formations. As a result, the valley walls where sandstone members are exposed have slightly steeper slopes than the shale and clay members. This leads to large overhangs and over breaks of overlying members.

Bedrock in the valley floor as exposed in the monolith foundations, for the most part, exhibited a minimal extent of slight to moderate bedrock weathering. The degree of weathering, depends on the type of material exposed at the original top of the rock. The sandstones and siltstones showed slight weathering to only about three fourths of an inch in depth. The shales and claystone showed and increased weathering pattern up to a moderate scale. The depth of penetration varied from six to ten inches.

The shale and claystone were observed to deteriorate, after their exposure. The observations were made on the walls of the excavated monoliths. These members were sloughing off in small pieces in sizes ranging from one eighth of an inch to one inch. To alleviate this problem, Aerospray 70 was applied and effectively sealed off these areas to minimize the effects of weathering.

3.08 Leaching and Solution Activities

Leaching and solution activities at the project are confined to calcite, and pyrite. The calcite was found in fractures and 1/8 inch to 2 inch seams. Pyrite crystals were found in small isolated pockets on the invert's of the downstream monoliths. Crystal forms of calcite and pyrite were found on the project. Crystal size was relatively small and typical for that mineral type.

The parent materials for these leached minerals are:

- A) calcite from the cementing medium in the clastic sedimentay rocks.
- B) pyrite from the small inconsistent coal seams.

These two sources are found in the rocks located in the upper elevation of the Conemaugh formation, or from the percolation of the ground water through the these porous rocks.

3.09 Ground Water

The ground water level at the project was determined during preconstruction subsurface exploration and surface observations. The ground water, as measured in drill holes and in piezometers appears to approximate the Greenup pool elevation 515.0 downstream and the Gallipolis pool elevation 538.0 upstream. Near the extended centerline of the existing dam, conditions of ground water are complicated by a perched water table and the transitioning effect between the upstream and downstream river elevations. In addition, the perched water table was encountered in a portion of the required excavation. Its location was adjacent to the extended centerline of the dam. This condition was expected due to the swampy condition of the location and because of the large amount of pervious material placed over low permeable clayey soils during the construction of the original lock. Before excavation and during construction of the new locks, control of the ground water was achieved by a slurry trench and dewatering well system. Ground water levels were monitored with piezometers. This system encompasses the entire project, approximately 4000 feet long by 900 feet wide. After excavation of overburden and blast materials, staining and odors showed evidence of low iron and sulfur content in the groundwater. In several cases, the lithologic boundaries between the sandstone and shale and between the shale and claystone showed moderate

ground water seepage. This water was controlled by using a Vactor Truck and/or pumps. In various locations on the project, artesian fow were encountered during drilling and grouting operations. The artesian flow was less than 0.01 cubic feet per five minutes per hole. The aquifers for the most part were the sandstones located in the downstream area of the project.

3.10 Engineer Characteristics of Overburden

Disturbed and undisturbed soil samples were tested at ORDL (Ohio River Division Laboratories). The results can be found in the design memorandums. The tests results provided the following information on the soil samples.

- (1) There were four major divisions: clay, clay sand, clean sand and a sand and gravel mixture. A sufficient quantity of suitable impervious and granular materials required were present to construct the structures.
- (2) The complete removal of overburden was necessary and all structures were founded on bedrock. During excavation, materials we stockpiled and used in construction of the dikes. Where the materials were placed depended on the type of material and the type of work being done at that time. Material foun unsuitable for construction was wasted in the pond area of the project. The materials were tested by Consulting Testing Laboratories (CTL) during excavation and placement. The material was classified, water content checked and gradation tests performed before it was used in the construction program.

3.11 Engineer Characteristics of Rock

In 1984 and 1986, representative rock samples from the six inch core borings were tested by Ohio River Division Laboratories (ORDL). The laboratories rock test data can be found in; Test Results, November 1984 and Design memorandum Volume 1 Phase II General Design Memorandum. The results of the test were used in selecting founding elevations and in designing the Lock Structures.

SECTION IV

EXCAVATION PROCEDURES

4.01 General

The contract Specifications for the Gallipolis Locks and Canal required a specific construction sequence. The major construction sequence are as follows.

- (1). Construction of the Downstream Cofferdam with Overflow section.
- (2). Completion of the Slurry Trench Cutoff Wall and Dewatering System,
- (3). Relocation of Flatfoot Creek before construction of the primary disposal dike

4.02 Downstream Coffer Dam

The construction of the downstream coffer dam and overflow section began on 4 June 1988 and was completed on 30 June 1988. The coffer dam consists of six sheet pile cells and five sheet pile arcs. The cells and arcs are sand filled with a twelve inch concrete cap. The overflow section consist of the sluiceway, timber needles and the slush grouted splash pad. Cells three, four and five have the openings for the needles and the sluiceways. The needles and sluiceways are twenty-two feet wide. The needles are constructed of eight by twelve timbers held together by a steel W12X53 beam. There are twenty-two timbers per sluiceway. At the end of the sluiceway is a twelve inch thick by twenty-six feet wide splash pad. If the needles are removed, the splash pad serves as erosion protection for the top of the slope. The face of the slope is protected by six to eight inch stone with a slush grouted surface. The cells

are anchored to the slurry trench on the east side and the existing locks on the west side. The connection to the existing locks was made with a concrete plug. Connection of the coffer dam cell to the existing guide wall was completed on 29 August 1988.

(See Book Four, Page 13, Picture 5 for the Downstream CofferDam)

The total amount of material used in constructing the Downstream Coffer Dam was: PS 31 sheet piling 51069.0 feet, sand fill 25,241.0 cubic yards, stone 150 pounds per square yard, slush grout 4,229.6 square yards and concrete 807.0 cubic yards.

4.03 Slurry Trench

In order to excavate below the water table by conventional methods, for the new Gallipolis Locks, a slurry cutoff wall was installed. The cutoff wall was constructed around the excavation, down through the alluvial sands into rock to prevent seepage into the excavation of the construction site. Dewater wells were installed in the excavation site to pump out ground water trapped, inside the cutoff wall. Piezometers were installed to check the efficiency of the cutoff wall and the dewatering wells. The efficiency of the dewatering system was approximately 98 percent. The north east area of the project was the only area found to leak, the problem was corrected adding a sump and pumping when needed. Piezometers were located both inside and outside the slurry trench. Construction of the slurry trench began on 25 March 1988 and was completed on 3 August 1988. The tie-in of the slurry trench to the coffer dam cells was completed on 22 August 1988.

The excavation of the overburden down to rock along the alignment of the slurry trench was accomplished with a 1266 Koehring backhoe with an extended boom. The contractor used a second backhoe, a 1066 Koehring for a standby. The average depth, including rock key was 70 feet.

The production of the excavation varied due to the type of material encountered. Problems in the excavation of the slurry trench were mainly related to the equipment's hydraulic system and engines. The keying into rock was completed by a Manitowac 3900 and a Link Belt FMC-518 crane, with a

chisel. The Link Belt also used a clamshell bucket. The clamshell was used to remove sand and chiseled rock debris from the bottom of the trench.

The Bentonite was stored on site in bulk form in silos. The silos were situated over two mixers each having the capacity of three and one half cubic yard. The mixers were capable of mixing one hundred cubic yards per hour. The mix design called for a marsh viscosity of 50 to 70 seconds, a specific gravity of not less than 1.10 and a sand content of not more than 10 percent. After mixing, the bentonite slurry was placed in a 1,600 cubic yard pit to hydrate. After hydrating for twelve hours, the slurry was pumped into the trench. This was done to support the walls of the excavation.

This method of excavation was very successful in that little spalling or cavitation was observed. The newly mixed and inplace material was tested for viscosity and unit weight. The only problem was a high sand content, which was corrected with a sand removal unit.

Backfill was designed to use the material removed during trench excavation. This material was tested every 500 cubic yards for gradation. Bentonite slurry was added to the back fill material until a slump of three to six inches was reached. The slurry and backfill materials were mixed together, twenty-five feet from the trench by a Komatsu D68P Dozer. This mixture was then transported to a Pug Mill Mixer, situated near the trench by a Link Belt crane, LS-108B with clamshell. This second mixing was to blend the materials and/to add fines or bentonite as needed. The material was then placed into the trench by the Pug Mill Mixer, until it was one foot from grade. Depth soundings were taken every twenty feet on in-place material twice a day.

A covering, of a heavily woven geotexitile material, was used as a filter cap. The geotexitile material was fifteen feet wide and centered on the open slurry trench. In the areas of the esplanade and where roads crossed the trench, a reinforcing material was placed. This situation was only 2 percent of the total length of the slurry trench. The reinforcing material was a dry blend of bentonite, sand, half inch crushed stone and one inch crushed rock. This mix design was controlled by volume. The bentonite component made up eight percent of the total volume. The remaining ninety-two percent was made up of: one part sand, one part half inch crushed stone and two parts of one inch crushed stone. The blended material was transported to the work area by three subcontractors. After reaching the job site, transit mixers placed the material on the filter cloth over the trench. The material was leveled by hand. Upon

completion of the reinforcement, a five foot lift of impervious clay was placed over the entire slurry trench.

(Reference Book Four, Pages 3,4, pictures 5-10)

4.04 Dewatering system

The dewatering system consisted of thirty-six wells and nineteen piezometers. The wells were installed within the area of excavation. Eleven piezometers were installed inside and eight outside the cutoff wall. The dewatering wells were installed by using the Holepuncher- sanding casing method. A twenty-four inch diameter casing (hole puncher annulus) was driven and jetted to rock. The casing was flushed until clean. The eight inch SDR 26 PVC pipe was installed and the filtering medium placed around it. The submergible pump and riser pipe were installed. The electrical connections were made at a later date. The piezometers were installed using the same methods as the wells. The only exception was the diameter of the pipe which was one and one-half inches. The combination of the slurry cutoff wall and the dewatering system, worked very well at the project. In June 1990, all the wells were disconnected and/or removed, except for the three on the downstream end of the project. The removal of the wells was at the contractors request.

(For more information see Appendix Section XI, pages 11-I-1 -11-I-10.)

4.05 Relocation of Flatfoot Creek

The relocation of Flatfoot Creek was necessary due to its location on the project. Before construction began, Flatfoot Creek meandered across the flood plain on its way to the Ohio River. Its location, corresponded with the proposed primary disposal area. The creek was directed into Ditch NO.4, which was constructed to replace the old outlet channel.(see vol.1 DACW drawing 16/52 and 16/75) Excavation of Ditch NO.4 was accomplished by a EX 1000 Hitachi Backhoe. Material removal was completed by 350CTK Payhauler. The removed material was placed in a stockpile for later use. Ditch NO. 4 has a nineteen percent slope and is twenty feet wide at the bottom. The side walls are protected from erosion by filter cloth and twenty-four inch stone.

(Reference Book four pages 5 picture 12 for flatfoot creek relocation)

4.06 Site Excavation

The excavation of the general work area began on 21 November 1987 and was complete on 11 February 1989. The general work area contain the work limits for rock excavation and the upper and lower guide walls. The contractor had planned to excavate the project area in two ways.

Step one was to remove as much of the material as possible using 651 Cat Scrapers. The limiting factor in using scrapers was the moisture content of the soils. When an area of saturated soil was encountered, removal by scrapers was difficult or not possible. The contractor used Cat Dozers to push the scrapers until both became immobile. The scrapers were then relocated to another section of the excavation.

Step two was the location of backhoes into that area and excavation continued. Three types of large earth moving backhoes were used, a 1066d Koehring, 1266d Koehring and a EX1000 Hitachi.

This two stage form of excavation worked quite well and was used extensively. When excavation of the overburden reached just above the rock, the scrapers were replaced entirely by backhoes. This was due in part to the varying elevation of the rock. This material was placed in dike construction, stockpiled, or in the waste area.

(Reference Book four, page 5, picture 11 for general excavation)

SECTION V

BLASTING

5.01 General

The specifications required, the contractor to submit a proposed blasting plan to C.O.E. This plan contained: Types of blasting material, typical shot layout and safety regulations for state and federal as they apply. The contractor was required to submit to the contracting officer, shot plans for each blast for approval. These plans contained: loads for each hole, stemming height, firing mechanism, delay sequence for each hole, and the seismic setup for that shot.

(For an example see appendix XI, page J) (Reference book four, pages' 6-7, pictures' 15-20 for blasting)

5.02 Presplit

Presplitting is a form of controlled blasting in which charges are fired in closely spaced holes. These holes are on the perimeter or outline of the excavation. This type of blasting is done to create a vertical and inclined plane of weakness. This plane controls the energy of the production blast. At Gallipolis, presplit holes were drilled two and one-half inch and three inches in diameter. The predominate hole size was two and one-half inches. The spacing for these shots were eighteen to thirty inches' center to center. The presplit holes were drilled, in all locations to final grade. Depth of presplit holes varies due to founding elevation. The maximum presplit depth was 29 feet, minimum depth was 2 feet.

5.03 Production blast

Production blasting is a form of blasting to break the mass into pieces. These pieces are of a size to be handled by conventional equipment. The drill

spacing is 2 x 2 foot center to center pattern. The blast is designed to allow the energy to move to an open face. This is done to reduce the damage to the rock. On the project, production blasting was complicated by the sudden changes in rock lithologies and the interbedded sandstones, shales, and claystone. These lithology changes could not be fully compensated for. The method used was to place stemming material, one foot of limestone chips in the bottom of the hole. This method sometimes worked well in sandstone, but not in the claystone and shale. The final product of the blasting were foundations with shot holes, and fractures. The shot holes varied in size from twelve inches to two feet diameter. The fractures radiated from one shot, sometimes connecting to another. The length of the fractures averaged about five to ten feet.

5.04 Line Drilling

Line drilling is a method of over break control. A series of very closely spaced holes are drilled on the perimeter or on parts of the monolith outline. These holes are not loaded with explosives. The use of line drilling at Gallipolis was extensive. Line drilling was used on inside and outside corners, and in where elevations changed between monoliths. It was also used for excavations, where the sills and the walls meet. The following is a breakdown of locations, where line drilling was performed and of lined drilled surfaces formed:

- (1). Main Lock Sills 11750.0 square yards,
- (2). Auxiliary Sills 11997.1 square yards,
- (3). Land Wall Steps 2136.5 square yards,
- (4). Middle Wall Steps 1349.0 square yards,
- (5). River Wall Steps 2734.4 square yards,
- (6). Culvert Steps 1408.0 square yards,
- (7). Corners 8189.0 square yards.

The use of line drilling was of limited success. In most cases the corners and edges of monoliths broke off. This happened during excavation or shortly after. These condition could have been caused by the blast or by the method of excavation. The blast could have caused intense fracturing, thereby weaking

the rock. In several cases failure was due to a nature weakness in the rock. These weakness were natural joints and fractures or slicken sides.

The surfaces of the line drilling were of a good quality, but were damaged during excavation. The use of large excavation equipment with ripper teeth, excavating 90 degrees to the foundation should not be allowed. If the equipment excavates parallel to the structure and does not pull material into the wall, further chances of damage to the line drilled face and foundation are reduced.

(Reference volume four pages 74-77 for pictures of over breaks)

(Reference Exhibit #10 for locations of line drilling page 14-I-1)

5.05 Statistic

Upon completion of the blasting, the total explosives used was 407,295 pounds. The powder factor was 1.20 pounds per cubic yard of rock. The material used was:

	<u>Primades</u>
321 cases of 2 x 8 unigel	#5 5900
2160 cases of 2 x 16 unigel	#6 5900
310 cases of presplit 7/8 x 24	#7 5300
122,000 feet of e-cord	#8 5300

#209 primer 200 3570 spacers 115,000 feet Noel lead line 5250 #17 caps ,1235 #100 caps

(For more information see appendix XI page J)

SECTION IV

ROCK EXCAVATION

6.01 General

The specifications reference rock excavation as: excavation that in the opinion of the contracting officer that requires continuous systematic blasting, ripping, or wedging of material. This includes loose boulders and rocks one cubic yard or larger. It also includes soft rock and earthen materials encountered below top of rock. At Gallipolis, there were three types of excavation in actual use:

- 1). General Rock Excavation,
- 2). Buffer Zone Excavation,
- 3). Sill Excavation.

6.02 General Rock Excavation

General rock excavation involved all areas, except the Buffer Zone and Sill Excavation. this type of excavation involved the removal of the bulk of the rock to reach final grade. There were several steps involved in this operation and more than one type of excavation. General rock excavation involved two main steps:

1). Excavation of the overburden to the top of rock and presplit the monolith outlines.

2). The production holes inside the presplit lines were drilled and shot. The shot material was excavated to produce an open face or relief zone. The final step was repeated usually two to three times. The specification required blasting of two-thirds of the final depth to reach monolith's final grade.

Equipment used to remove the shot material was 1266 Koehring backhoe, Hitachi EX1000 backhoe, Case 9170 tractor and Catapiller D8 dozer. Material was hauled to the waste area by 350CTK Payhaulers.

(Reference Book four, page 7, pictures 21,22 for rock excavation)

6.03 Buffer Zone Excavation

The Buffer zone was used in critical areas to lessen the blast impact. The buffer zone excavation was in the following areas: Critical areas: culvert turns, areas around the sills, and Inlet structures and R-78 to R-95.

The contractor did not use any specialized equipment in this phase of excavation.

Buffer zone excavation worked very well around the sills, but in turns or corners it was of limited success. The use of this type of excavation is a asset and should continue to be used.

Procedure

The buffer zone excavation was performed as follows:

- 1). General rock excavation material was broken by production blasting, and excavated to provide relief for the buffer zone excavation.
- 2). The Buffer zone material was drilled and loaded with a light shot that was directed into the relief zone provided by the previous excavation. The excavated material was hauled to the waste area. The Buffer zone excavation was performed to protect the

Integrity of foundations, where several required blasting intersected each other.

Buffer zone excavation did not achieve the best results, due to intrusion of shale and claystone lens. Under different lithological conditions, buffer zone excavation would be more successful. Buffer zone excavation should continue to be used in areas, where several walls and blasts intercepted.

(Reference Exhibits Drawing #11 page 14-J-1)

6.04 Sill Excavation

Sill excavation included all the following areas: Bulkhead Sills, Miter Gate Sills, and Emergency Gate Sills. The procedural difference in Sill excavation was produced by the blasting. In blasting the sills, every other hole was loaded. The loads were reduced to prevent the rock from over breaking. The blast results were larger pieces of material. These larger pieces had to be reduced in size by mechanical means. The contractor did not use any specialized equipment to do Sill Excavation. The equipment used was the same as in General Rock Excavation.

The results of sill excavation depended on rock type and quality. Sill excavation worked well in the downstream sills due to the quality of the sandstone. However, the upstream sills were founded on and cut through shale and claystone, and here sill excavation did not work as well. Instead of every other hole, every third hole should have been loaded.

Attention to rock types, hardness, and overall condition of the material is essential in achieving good results from blasting.

6.05 Statistic

Upon completion of rock excavation, the totals were: General Rock Excavation 299,209.0 cubic yards, Buffer Zone Excavation 38,564.8 cubic yards, Sill Excavation 19909.4 cubic yards. The total rock removed was 357,683.2 cubic yards.

6.06 Aerospray 70 Binder

The specifications required a protective coating to be applied within twelve hours after monolith excavation. The protective coating was applied to designated vertical and horizontal surfaces. The binder was to be applied in two coats with 46% to 48% solids.

Aerospray 70 is a polymeric soil stabilizer. The stabilizer function was to reduce or eliminate surface erosion. The polymeric binder was used to stabalize exposed claystone, clay and indurated clay in the presplit side walls of the monoliths. Aerospray 70 was applied using a airless paint unit.

On one occasion, the binder was applied to the invert of Monolith L-3. Due to the low absorption of the clay, the binder laid on the surface until drying. The invert became very slick due to the application of Aerospray 70. The slick surface created a safety problem and no protective benefits were observed. No further application of Aerospray 70 on other invert was attempted. There were two correctives measures employed on problem foundation:

- 1) Reduce the time between foundation preparation and placement. This reduces the time the foundation is open to the elements.
- 2) Keep the foundation from going threw the wet/dry cycle. This keeps the foundation at a constant moisture content, and does not allow it to spall or peel.

Using these measures reduced the destructive consequences of the elements on a foundation.

The binder was applied as soon as time and the elements allowed. It was mixed 50% binder to 50% water. This ratio was as thick as could be sprayed with the contractor's equipment. Upon completion of the project 1,876.5 gallons of Aerospray 70 had been applied.

The use of Aerospray 70 worked well in stopping surface weathering. But on one occasion, at monolith R-47 water built up behind the binder until the rock failed. The slide area stripped of all lose rock and replaced with, approximately 45 cubic yard of concrete. Reference volume 4, picture 252. The use of this product should continue to be applied in all excavations, which involves clay and shale materials

(See appendix book 4, page 8, picture 25, for binder application)

SECTION VII

FOUNDATION ROCK ANCHORS

7.01 Anchor Bars

Anchor bars in rock were required for the Miter Gate Sills in both chambers, upstream and downstream. The rock anchors were constructed by:

- 1). Drilling a one and five eights inch hole,
- 2). Placing a grout Jacking pad around the hole,
- 3). Using a twenty foot plastic pipe and high pressure air to clean the holes,
- 4). Inserting Fastloc T Resin cartridges, X number of fast set and Y number of slow set,
- 5). The number ten anchor rods were inserted using the drill. The anchor rod was rotated while advancing through the resin cartridges.
- 6). The resin required a certain period of time for sitting. Upon completion of the set time, the bearing plate was positioned on the grout pad. The retainer nut was then placed on the rod and tighten until snug,
- 7). The Jack (a Enerpac model LH-2506) was positioned and the rod tensioned to thirty-three kips. The retainer nut was then tightened.

(Reference Book four, pages' 61-62, pictures' 207-212 for Rock Anchors)

7.02 Completion Phases

The Rock anchors were completed in two phases. The first Phase was the downstream sills. The second phase was the upstream sills.

Phase I

15-19 March 1990, Fifty-five anchor bars were set in the downstream Main Lock Miter Gate Sill.

An average of five fast set and seventeen slow set fastloc cartridges were used per hole.

20-22 March 1990, Fifty-five anchor bars were set in the Auxiliary Miter Gate Sill. Five to six fast set and sixteen to seventeen slow set cartridges were used per hole.

Phase II

17-20 May 1991, Fifty-six anchors were set in the upstream Main Lock Miter Gate Sill. An average of six fast set and sixteen slow set cartridges were placed in the holes. One rock anchor was replaced due to the contractors welding and cutting on the metal rod. This caused the tensioning sequence to be out for this sill.

20-23 June 1991, Fifty-five anchors were set in the Upstream Auxiliary Miter Gate Sill. Five to six fast set and fifteen to seventeen slow set cartridges were used.

The anchor and resin system functioned as required. The artesian flow did not create a problem, during anchor installation.

7.03 Statistics

The total drill footage was 5,720 linear feet. Each Sill's footage was 1,430 lineal feet or one fourth of the total. Two hundred and twenty anchor rods were set for a total length of 5,500 linear feet. There was 1201 fast set and 3639 slow set cartridges used. The average number of cartridges, installed per hole was 22.

SECTION VIII

CHARACTER of the FOUNDATION

8.01 Foundation Surface

The foundations excavated at Gallipolis varied in depth from 2 feet to 28 feet as measured from a average top of rock. The final elevations were chosen using cores taken from each monolith. The final foundation surfaces for the various components of Gallipolis Lock Replacement Project were controlled by the bedding structures in the shale and claystone members of the Conemaugh Formation or by shale lens or seams in the sandstone.

The foundation surfaces consisted of thin to massive coarse-grained micaceous sandstones in the downstream area grading to claystone and shales in the upstream area. Discontinuous shale lens and seams were found in the sandstone lithologies. The seams and lens varied in thickness from a half a foot to two feet. These lens and seam were encountered in the west vertical wall of the River Wall and in the foundation inverts. The shales had clay and calcite seams varying in thickness from 0.25 to 3 inches. Calcite was found in seams from .5 to 3 inches. These were located in the inverts of many foundations in the upstream monoliths. The seams of clay and calcite were removed and repaired using dental concrete.

The foundation for the River Inlet Structure was founded on shale. This structure was presplit and excavated by a 1266 Koehring backhoe. No production blasting was performed. The shale was soft to very soft in hardness and was in thin bedding planes. When excavated these bedding plans were easily broken. The foundation surfaces remained good, if after exposure it was sealed with concrete within 24 to 48 hours. When this did not happen, large areas had to be reworked to remove lose material and dental concrete used to repair them.

8.02 Condition of Foundation Rock

The condition of the foundation rock for the lock structures ranged from poor to good. The physical properties of the foundation sandstone, siltstone, and shales were well suited for founding surfaces. Claystone and weak shales were not intended for foundations. Some seams and lens were left in place and sealed off with dental concrete. These areas were left, due to the closeness of the indurated clay.

The primary problem concerning the foundation rock was the bedding planes and the softness of the clays and shales. In their natural state each rock type causes problems in blasting and excavation to grade. These problems included rock overbreak and dammage to the foundation invert surface. This was caused by the brittleness of the material and the bedding planes. However, these problems were sometimes anticipated from information derived from exploratory borings. If anticipated, blast plans were modified by reducing loads or spreading out the hole pattern.

The most detrimental factors concerning the foundation rock were the numerous clay seams and broken zones. Most of these were contained in the upstream shales and claystones. Although these structures were treated, by the use of dental concrete, they could still represent an inherent weakness in competent foundation rock.

(Reference Dental Concrete Appendix Section XI, page F) (Reference Book four, pages' 64-74, pictures' 214-248, for dental repairs)

8.03 Water

Ground water caused various degrees of deterioration in the clays and shales. The most notable was the contact between the claystones and/or indurated clays and shales. The deterioration ranged from minor to severe in the shale and clays. A example of this deterioration is in the upstream sills and some of the Land Culverts. In these areas, the rock was excavated and back filled with a granular material, the specification call this protective earth cover. Months later, after excavation of the granular, the rock was in poor condition. This was evident by the open bedding plans, broken corners and overall

decrease in hardness at the surface due to weathering The problem areas were isolated and sealed off by dental concrete.

8.04 Foundation Cleanup and Preparation

The specifications describe foundations as the rock surfaces upon which concrete structures are placed. The preparation and cleanup of these areas was accomplished by light Equipment and hand tools in combination with high pressure air and water.

The use of rubber tire equipment on cleanup was extensive. The contractor used a Case 9170 Tractor to remove the remaining debris from the foundation. The air/water combination was used to wash and remove dirt and small rocks from the invert. The hand tools included: chipping guns, small jackhammers, spud bars, and shovels. The hand tools were used to remove drummy rock. The following was the sequence of events in foundation cleanup and preparation.

- 1). The case tractor removes debris left by the excavation of the monolith.
- 2). The fine material is blown or washed off by the combination of air/water.
- 3). The Project Geologist sounds the foundation for drummy rock. The bad rock was marked for removal with orange paint.
- 4). The cleanup crew removes the drummy material by chipping guns, pry bars shovels and other hand tools. Then theoundation is washed with high pressure air and water.
- 5). The geologist inspects the foundation again for drummy rock. At this point, he will either approve or remark the foundation again. If the foundation was remarked, the sequence starts at step 4. These event were repeated until the foundation was approved

(Reference Book Four, page 8, pictures 23,24)

SECTION XI

FOUNDATION TREATMENT

9.01 General

The foundation treatment for Gallipolis Locks consisted of the following.

- Installing a grout curtain under each of the three walls.
- 2). Drilling weep holes in the Main Chamber and Auxiliary Chamber Lock floor pavement areas and the Auxiliary Chamber Lock Laterals.
- 3). The final rock surface treatment on the foundations was dental concrete. Dental concrete was used to repair depressions, broken zones, exposed clay seams and open joints.

9.02 Curtain Grouting

A grout curtain was placed beneath each of the three walls to reduce leakage through the rock under the locks. This curtain was constructed in two zones. Zone one was from founding elevation to elevation 470. Zone two was from elevation 470 to elevation 460. These curtains extend from 13+75B to 1+25A. The location of each line is as follows: River wall 78.05 feet from construction base line B; Middle wall 76.05 feet from base line B; Land wall 230 feet 1.5 inches from base line B.

(See exhibits II, page 14-K-1 for more information)

The grout curtain was developed by drilling thru preformed holes inside the walls. Metal pipe was embedded in concrete from founding elevation to the culvert invert and to the top of some monoliths. Therefore, drilling of the 1 7/8 inch holes began at founding elevation for each monolith within the limits of the grout curtain. Founding elevations for the various monolith foundations vary

throughout the project. The spacing of the holes along the grout line was 20 feet between primaries with two tertiary and one secondary hole between. Hole spacing was five feet and all holes were drilled vertical. Drilling of these holes was done in zones and sections. Zone one consisted of fifteen feet or less of rock and zone two consisted of ten feet of rock. All grout holes extend into zone II. The sections, for drilling and grouting were 200 feet in length. The drilling and grouting operations were not permitted at the same time in the same section.

As a rule, all primary holes in a zone were drilled and grouted before secondary holes were drilled. This drilling began on the next zone. As a general rule, if a hole took over 100 bags of cement in a zone, split space holes were required on both sides of that hole. The following procedure was used for the grouting program.

- Pressure tests and grouting pressures were regulated so that the
 occurred pressures would not exceed burden pressures. Burden
 pressure was calculated using 1 pound per square inch for each
 foot of rock and 1/4 pound per square inch for every foot of
 embedded pipe. Pressure was measured at the top of the grout
 hole.
- 2). Pressure grouting of a hole was required when during a 5 minute pressure test, water injected exceeded the average of 0.2 cubic feet per minute.
- 3). Pressure grouting for a particular zone was considered sufficient when grout injected either reached refusal or the hole refused to take grout at 3/4 of the grouting pressure.

To expedite the grouting program, the work was performed in three phases.

Phase one was between 23 March 1990 to 20 June 1990. This first phase consisted of grouting of the downstream downstream sills, 813 feet of the River Wall and 403 feet of the Middle Wall.

Phase II was between 8 January 1991 to 15 March 1991. It consisted of 638.5 feet of the River Wall, 1048.5 feet of the Middle Wall, and 852.5 feet of the Land Wall

Phase III began on 14 August 1991 and ended on 27 October 1991 and consisted of the grouting of the upstream sills, Miter Gates and Emergency Gate sills.

9.03 Drilling Procedure

Drilling the 1-7/8 inch diameter began after the monolith had reached the final grade for the invert of the culvert. Drilling of these holes was accomplished by means of Semico, Longear, Ackor, and Diamac Drills. Phase I drilling was completed by a Semico, Long Year Drill. The Semico drill was a pneumatically powered diesel driven drill. The Long Year was skid-mounted, pneumatically powered diesel driven. Phase II and III drilling were completed by a Diamac and a Ackor Drills. Both drills were electric, pneumatically powered and were skid mounted. Movement of the drills was accomplished by forklift.

Bits used during the drilling varied with the material. In areas where sandstone, siltstone, and shale were found, an AW sized stratapack (three finger bit) was used. In the softer shale and claystone, a AW Roller Cone bit was used. Several other bits were tried, such as a Geopack bit, a Stratpack Button bit, and a Three Wing Carbide Drag bit. None of these bits were as successful as the Stratapack (three finger bit) or the Roller Cone. Every hole was tested for foreign materials with an AX size magnet before drilling began.

The only problem during the drilling and grouting operations, was the introduction of wood, steel, and other foreign material into the preformed holes.

9.04 Washing Holes

Upon completion of the drilling, each hole was cleaned of drill cuttings and muck. A three-quarter inch diameter black plastic pipe was inserted into the drill hole until the bottom was reached. High pressure water was injected into the hole. The water injection was continued until the water return was clear. When this condition occurred and persisted, the pipe was moved up and down about two feet in height. This was to assure the removal of all foreign material.

9.05 Water Test

The water test consisted of the following steps.

- 1). Inserting a two inch mechanical packer into the grout hole. The packer was seated at a depth of one foot.
- 2). Attaching a two inch water line with cubic foot meter.
- 3). Use the overburden method to Calculate the pressure to be used.
- 4). Start introducing water into the hole. Continue introducing water until pressure equals the calculated.
- 5). At that point begin the five minute test. During this process, holes on either side are checked for connections. If there are connections, Packers are placed in that hole and left open. These holes are retested with the valves closed and the two readings are compared. If the test results are greater than 0.2 cubic feet per minute the hole is groutable. If the results are less than 0.2 cubic feet per minute, the hole is considered a tight hole, and the test is over.

9.06 Grouting

The location of the grout plant coincided with the section being grouted. The plant was on wheels and was moved to each succeeding section. This was accomplished by a crane or forklift. The grout holes were located in a single line, in the tunnels of each wall. Grouting began with the primary holes zone one and ended with the secondary holes zone two. The grout mixes were based on the preceding water test. The starting mix was standardized to prevent problems. The standardized mix was four cubic feet of water to .94 cwt of type two cement. If the injection rate, of the grout did not decrease after 14.1 cwt to 18.8 cwt, the mix was thickened. The mixes were thickened by the removal of half a cubic foot of water. This procedure continued until refusal or the 94 cwt limit was reached. During grouting operations, the rate of injection was continuously monitored and the water-cement ratio correspondingly adjusted as needed.

The grout mixes consisted of:

- (1) water: The requirements for a mixing agent per the specification were: water that was fresh, clean and free of injurious amounts of sewage, oil, acid, alkali, salts or organic matter. The contractor submitted samples of water from the Ohio River and the dewatering system that surrounds the project. The Ohio River sample was turned down as a mixing agent due to the high content of chemicals, organic and iron. The dewatering system provided water that contained no adverse elements and was approved as the mixing agent.
- (2) Cement: The specifications on cement called for a Portland cement, that would conform to ASTM C 150-85A, type one or two. It was to be stored in a dry, weathertight and properly vented area. The cement was provided by Armstrong Cement Manufacture Company. Armstrong was a federal inspected and approved source of cement. The cement used in grouting was a low akali type two. The cement was furnished in ninety-four pound bags and was shipped to the project in lots of five hundred and fifty bags. At the project, the cement was stored in a metal building two hundred yards south of the Resident Engineer's Office. One hundred and twenty bags or three pallets were placed in the culvert, near the grout plant. The palletized cement was protected from moisture by plastic shrink rap. At the end of the shift, unused cement in open pallets was covered with plastic. The cement was placed through a #8 screen to remove any large pieces. This procedure was followed so that grout mix was homogenous.

9.07 Statistic

To place the grout curtain at Gallipolis, statistically 2153.26 hundred weight of solids was placed in 10,832.5 lineal feet of drilling. This averages out to 0.199 hundred weight of solids per foot of drilling. This average was below the 2 cwt/ft. estimated in the contract. The sandstone lithologies took more grout than the shale and claystone. The land wall section took more grout than the other areas. There were no unusual problems encountered during the three phases of grouting.

(Reference appendix section XII, pages 12-N-1 to 12-P-14 for more information on grouting.)

9.08 Weep Holes

A weep hole is a relief hole drilled into rock or overburden. After the hole is drilled, it is lined with perforated pipe, or backfilled with pea gravel. This design relieves, the build up of hydrostatic pressure from below the structure. This is done to prevent the structure from moving or floating. The locations of the weep holes at Gallipolis are the Lock Floor Pavement areas and in the Lock Laterals. The specifications state that the holes will be three inches in diameter and ten feet into rock. All weep holes will be thoroughly cleaned using air and water. They will be kept clean and plugged until the contracting officer directs the removal of the plugs. The contract for Gallipolis, did not call for the pea gravel backfill. The contract was modified to correct this problem. The weep holes were installed in accordance with the specifications.

(For more information see section XIV, 14-L-1, 14-M-1, 14-n-1)

Auxiliary Chamber

The auxiliary Chamber contains two areas of weep holes:

- The upstream Lock Floor Pavement area is located between the upstream Miter Gate and the Bulkhead Sill. It is an area of 638 square yards and contains 154 weep holes.
- 2). The Lock Laterals are located from station line 7+66.0B to 4+90.0b. There are twelve lines with forty holes per line for a total of 480 holes.

Main Chamber

The Main Chamber contains only one area of weep holes, the Lock Floor Pavement. The Lock Floor is an area of 462 square yards and contains 118 weep holes.

All holes were drilled using a Acker drill. There were only two problems connected with the weep holes. The contractor laid out a section wrong. The second problem was the specifications did not require, the weep holes to be

backfilled with a filter material. The contractor repaired the layout problem, by backfilling two holes with concrete. The contractor redrilling four new ones to correct the problem. The contract was modified to include the addition of a filter material, which was pea gravel. After the completion of the backfilling operations 67% of the weep holes were making water.

(For drilling information see Appendix Section XI, page L)

(For layouts and Numbering system see Exhibits, Section XIV pages #13, #14, #15)

SECTION X

POSSIBLE PROBLEM AREAS

10.1 River Wall Intake structure

The foundations for the Intake Structure are made up of shale and shale interbedded with clay. These two rock types, in this area are very soft and decay quickly. The exposure to the turbulence at the Intake Structure could cause a serious erosion problem. This should also include the River Wall culverts of the intake structure. All these structures are exposed to the river by their axis.

10.02 Removal of the Concrete Bolsters, Main Chamber

The concrete Crane Bolsters were removed by explosives on 10 December 1991. The removal was after, the completion of the three phases of grouting. The prime contractor used a professional blasting company, called VIBRA-TECH Engineers. The powder factor used was less than one pound per cubic yard of material. The VIBRA-TECH EVERLERT II seismograph equipment was used on each shot and a recording made. The worst reading that was recorded was shot #5. The results are as follows: air cal 137 db, tran. cal 1.02 inch per second, vertical cal 1.02 inches per second, long cal 1.04 inches per second. The recordings reflect little if any of the blast energy or vibration was directed to the foundation.

The use of explosives could have reopened joints and fractures, that were repaired during the grouting. Another concern, is the blast could have cause micro-fractures in the foundations. In both cases, the functioning of the locks could increase the problem. This is due to the raising and lowering of the pool

inside the chamber. At this time there is no way of checking to see if there really exist a problem of this type or of monitoring it. The piezometers that were to be placed in the backfill, behind the River and Land Walls were deleted.

Preventive measures

The protection of the intake structure could be done by placing riprap on the upstream side. This would reduce the erosional effects of the rushing water. The piezometers should be installed to verify if there could exist a problem in the foundation due to the blast removal of the crane bolsters.

PUMPING TEST ON GROUNDWATER CONTROL SYSTEM FOR GALLIPOLIS LOCK EXCAVATION Ohio River

Report to

U S ARMY CORPS OF ENGINEERS HUNTINGTON DISTRICT Huntington, West Virginia

November 22, 1988

Bu

CHARLES MANSUR, PE GEOTECHNICAL ENGINEERING CONSULTANT

PUMPING TEST ON GROUNDWATER CONTROL SYSTEM FOR GALLIPOLIS LOCK EXCAVATION

INTRODUCTION

In order to facilitate digging the excavation for construction of the second Gallipolis Lock, a slurry cutoff wall was constructed around the excavation down through the alluvial sands to rock to prevent seepage into the excavation. Thirty six wells were installed within the area of the excavation to pump out the groundwater trapped within the cutoff wall. Eleven piezometers were installed inside and eight outside of the cutoff wall for checking the efficiency of the cutoff and predrainage system. The locations of the cutoff wall, predrainage wells, and the piezometers are shown on Plates 1 and 2.

The specifications for this work required that a full scale pumping test be made on the predrainage well system after installation of the slurry wall and the well system. The slurry cutoff wall was completed to the cellular coffercells at the downstream end of the excavation on 3 Aug 1988. Connection of the slurry cutoff to the coffercells was completed on Aug 22; the tie-in from the cells to the guidewall for the existing lock was completed on Aug 29 (see Plate 1). These small openings in the cutoff wall were still open at the time the pumping test was made. All of the predrainage wells had been installed by the time the pumping test was made but Wells 22 and 23 had been removed by the contractor because of interference with his excavation before the pumping test was made.

All of the piezometers shown on Plate 1 had been installed but Piezs 6, 7, 12, 13, and 17 had been removed by the contractor prior to start of the pumping test. Piezs 12, 13, and 17 were reinstalled prior to start of the pumping test. Piez 19 was also installed just prior to start of the pumping test. Piezs 4 and 10 were located adjacent to Wells 18 and 29, and were not included in this study. Although the pumping test on the predrainage well system was supposed to have been made prior to the start of any excavation or before any individual wells were pumped, the contractor had started to pump Wells 1, 2, 3, 4, 5, 6, 7, and 8 on Aug 4. [A few of the wells may have been pumped prior Aug 4.]

Pumping Wells 1-8 was started on Aug 5 shortly after the slurry cutoff wall was completed. Pumping the remainder of the predrainage wells was started at 7 pm on Aug 25 and was continued until Oct 30 when the groundwater within the excavation had been lowered about as low as practical by pumping from the predrainage wells.

CHARLES MANSUR, P E Geotechnical Engineering Consultant

Re: Charles Mansur (Consultant)
Contract #DACW6987-D-0037
Geotechnical Engineering Monitoring
Pumping Test on Groundwater Control System
for Gallipolis Lock Excavation

Dear Mr Avery:

Submitted herewith is my analysis of the pumping test recently made on the groundwater control system for the excavation for construction of the second Gallipolis Lock in accordance with the above referenced contract.

If you have any questions regarding my analysis of the pumping test made on this system, I shall be glad to answer them.

Sincerely,

Charles Marson

Charles Mansur, PE Consultant

U S Army Corps of Engineers

BASIC PUMPING TEST DATA

Basic groundwater and pumping test data are summarized in the following tabulation.

•	
Started pumping some wells	In June 1988
Started pumping Wells 1-8 in downstream area of excavation	Aug 5, 1988
Average groundwater level within excavation on 16 June 1988	530.3 msl
Average groundwater level within excavation on 25 Oct 1988	505.0 msl
Predrainage wells installed	36
Predrainage Wells 22 and 23 removed by contractor prior to start of pumping test on Aug 25	2
Number of wells pumped during pumping test and until Oct 25	34
Start of pumping test7:0	0 pm 25 Aug 1988
Completion of pumping test	0 pm 27 Aug 1988
Duration of pumping test	48 hours
Total pumping time after 25 Aug 1988	60 days
Observation of piezometers continued for 60 days after pumping test (to)	30 Oct 1988
Maximum capacity of pumps in wells	300-400 gpm
Average rate of pumping on 8:00 pm 25 Aug 1988	275 gpm/well
Average rate of pumping on 7:00 pm 27 Aug 1988	227 gpm/well
Upper pool elevation at start of pumping test	539.3 msi
Lower pool elevation at start of pumping test	516.6 msl
Fall in pool levels during (August 25-27) pumping test	0.3 ft
After completion of pumping test, upper and lower pools rose	0.5* ft
Average groundwater level in excavation at start of pumping test	521.0 msl
Average groundwater level in excavation after 64 days of pumping	505.0
Average water level in predrainage wells after 64 days of pumping	504.2

Average drawdown in excavation

During 48-hr pumping test Piezs (2, 3, 5, 9, & 11)
--

The GWT at each of the piezometers is shown on Plate 1 for 16 June 1988 prior to closure of the cutoff and 25 October 1988 (after 60 days of pumping 34 wells)

ANALYSIS OF PUMPING TEST DATA

As installation of the groundwater cutoff wall around the excavations had a significant effect on the groundwater level, the sequence and dates of construction of the cutoff wall are given in the following summary and are plotted on Plate 4.

Installation of slurry wall started going north at about Piez 15	13 Aug 1988
Installation of slurry wall to Piez 12	24 May 1988
Slurry Wall tied into upstream end of Lock	29 June 1988
Installation of slurry wall started going south at about Piez 15	30 June 1988
Completed (slurry) cutoff wall to within about 40 ft of downstream coffercells	3 Aug 1988
Driving sheet piles from (slurry) cutoff to cells completed	22 Aug 1988
Driving Z piling from cells to downstream guide wall completed	29 August 1988

The piezometric data plotted on Plate 1 show that the GWT inside of the lock area on 16 June 1988 sloped from about El 533 at the upstream end of the excavation area to about El 525 at the downstream end of the excavation area. The GWT outside of the cutoff wall sloped from about El 538 (slightly below the upper river pool) at the upstream end of the excavation area to about El 519 (slightly above the lower pool) at the downstream end of the excavation area. [This is about as might be expected with an upper pool level of El 539 and a lower pool level of El 517.] Once the cutoff wall around the lock area was closed, the GWT inside of the lock area more or less leveled out.

Pumping predrainage Wells 1, 2, 3, 4, 5, 6, 7, and 8 at the downstream end of the excavation area, lowered the GWT inside of the lock area from El 534 to 527 (or about 7 ft) at the upstream end of the excavation area and from El 525 to 515 (or about 10 ft) in the downstream end of the excavation area, prior to start of the pumping test.

The GWT inside and outside of the excavation area prior to closure of the cutoff wall and start of any pumping of the predrainage wells is shown in brackets () for the various piezometers on Plate 1. Pumping all of the predrainage wells lowered the GWT 9 to 10 ft at the upstream end of the lock area, 5 to 6 ft at the center, and 6 to 7 ft at the downstream end of the lock, during the 48-hr pumping test. Pumping the wells for another 60 days lowered the GWT within the excavation down to an average elevation of 505.0. The GWT both inside and outside of the cutoff wall is also shown on Plate 1 for each piezometer after 60 additional days of pumping all of the wells.

The average drawdown (DD) of the GWT at Piezs 2, 3, 5, 9, and 11 within the lock area is plotted vs Elapsed Pumping Time (T) for the 48-hr pumping test on Plate 3.

[As Piezs 2, 3, 5, 9, and 11 all exhibited similar drawdown characteristics, only these piezometers were averaged to plot the average DD curve on Plate 3. Piez 1 first seemed to be inoperative and was not included with the plotted data. Why Piez 8 behaved initially so differently than the other piezometers in the lock area is not known; however, the more rapid DD in Piez 8 can probably be attributed to its being located near the downstream wing wall and where there was a smaller zone of water to be pumped out by the predrainage wells along the downstream lock walls.]

The average rate of pumping, Q_w, at the start of the pumping test (8:00 pm 8/25/88) was 275 gpm; after pumping for 48 hrs, the average rate of pumping per well had diminished to 227 gpm.

Prior to starting installation of the cutoff wall around the excavation for the Gallipolis Lock, the upper pool at the existing lock was at El 538.2 and the groundwater table (GWT) at the upstream end of the excavation area was probably at about El 536. The GWT at the downstream end of the excavation was at about El 524 with the lower pool at El 516. The above differential of 12 ft in the GWT from the upper end of the excavation to the lower end can be attributed to the natural slope of the seepage gradient around the lock prior to construction of the cutoff wall out into the valley. The average GWT in the excavation area prior to construction of the cutoff was probably about El 530.

Shortly after the start (Apr 13) installation of the cutoff wall, the GWT within the excavation area started to fall and continued to fall at an increasing rate as the cutoff was completed around the excavation down to the closures at each end of the sheet pile cells at the downstream and of the excavation. This falling of the GWT within the excavation area can be attributed to pumping

a predrainage well on two and to drainage downstream to the lower lock pool as seepage from the upper pool is progressively blocked by construction of the slurry cutoff wall. Completion of the slurry cutoff wall on Aug 3 combined with starting to pump Wells 1-8 produced a marked lowering of the GWT within the excavation area (See Plate 4). Completion of the cutoff wall to the sheet pile cells (Aug 22) and starting to pump the remaining (26) predrainage wells on Aug 25 produced a rapid lowering of the GWT within the excavation area. Pumping all of the predrainage wells, except Wells 22 and 23, for an additional 60 days after the 48-hr pump test lowered the GWT in the excavation area to an average elevation of 505.0; the GWT at each piezometer during this pumping period is also plotted vs date on Plate 4 and is shown at the end of the pumping period on Plate 1. The water level in each of the wells prior to start of the pumping test and 64 days later is also plotted on Plate 1. It may be noted that the water level in the wells was maintained at El 503 to 506 after Sept 1.

The average groundwater level in the lock area had been lowered to approximately El 521 by the contractor pumping Wells 1 through 8 prior to start of the pumping test. This previous drawdown (DD) of 9 ft was added to the DD's obtained during the pumping test and then the total DD plotted vs Elapsed Pumping Time on Plate 5, the basic graph of which was copied from Plate 11 in the report: Study of Dewatering Excavation-Gallipolis Locks and Dam Replacement - Ohio River dated 7 Oct 1983, by Mansur. When allowance is made for the capacity of the pumps being a maximum of 300 to 400 gpm rather than the 600 gpm as used for the computed graph on Plate 5, it appears that the predrainage wells and pumping system performed about as expected.

The upper and lower pool stages prior to, during, and after the pumping test are plotted on Plate 4. It may be noted that both the upper and lower pools were relatively stable, during the 48-hr pumping test, but gradually rose about 0.5 ft thereafter.

After the start of pumping Wells 1-8 in the downstream area of the excavation on Aug 5, the water level in Piez 14 outside of the slurry cutoff wall fell about 3.5 ft until the connection between the slurry wall and sheet pile cells was closed on Aug 22 (See Plate 4). This fall in the GWT at Piez 14 can probably be attributed to redistribution of the groundwater flow pattern around the blockage in the valley created by closure of the slurry cutoff and seepage from outside of the slurry wall into the area being predrained by starting to pump Wells 1-8, which lowered the GWT in the downstream end of the excavation area to about El 516 on 5 ft below what the GWT at Piez 14 had been. Similar, but less, effect of starting to pump Wells 1-8 with the gap at the sheet piling cells open, can be noted from the fall of the GWT at outside Piezs 15 and 16 which were farther from the gap in the cutoff wall at the coffercells.

After the gaps in the cutoff wall were closed, the fall in the GWT at the outside piezometers diminished. However, the GWT at all of the piezometers (12-17) outside of the slurry cutoff wall gradually fell 0.5 to 1.0 ft after pumping the entire predrainage system was started on

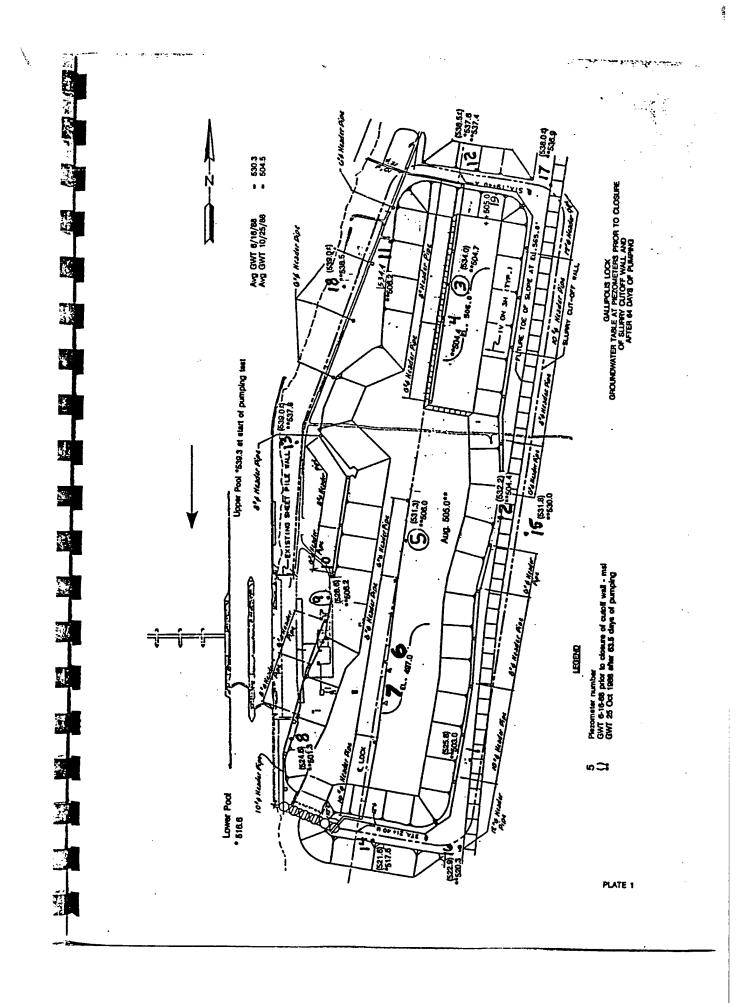

Oct 25. As the groundwater level was lowered inside of the slurry wall, there must have been some minor leakage through the slurry wall and/or through the underlying rock into the area being dewatered.

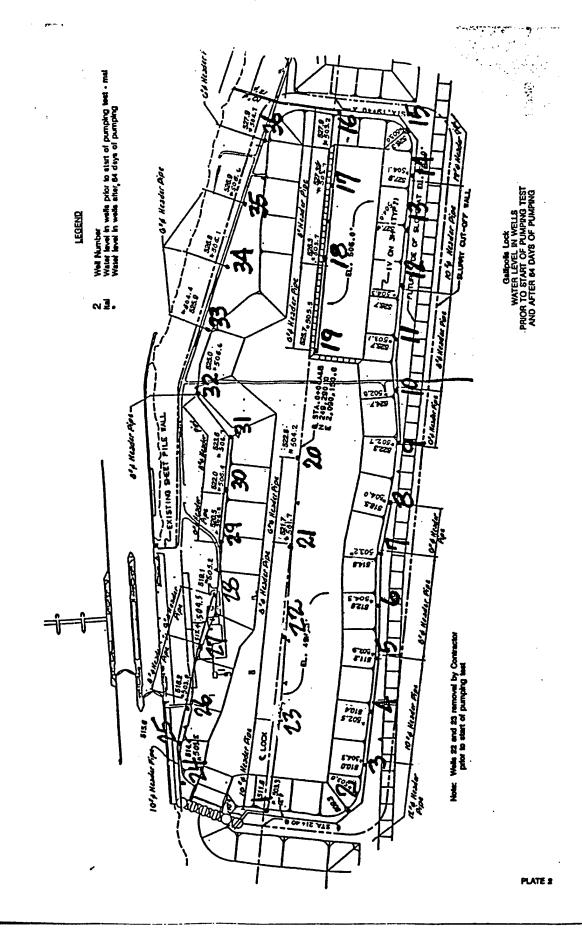

Regardless of whatever leakage there is through or beneath the cutoff wall, pumping the 34 predrainage wells lowered the groundwater therein about 25 ft during 60 days of pumping, or within about 4 ft of the drawdown calculated (see Plate 5). Had 600-gpm pumps been used, as assumed in the theoretical calculations, rather than 300 to 400 gpm pumps, the check between the computed and actual drawdowns and well flows would have been even some better. In any event, the cutoff wall and predrainage system seems to have performed basically as planned.

Charles Mansur, PE

Contract #DACW6987-D-0037
Geotechnical Engineering Monitoring
Gallipolis Lock
Pumping Test on Predrainage System

Dear Mr Avery:

Submitted herewith is my analysis of the pumping test recently made by the contractor (GLR Constructors) on the predrainage well system for the excavation for construction of the second Gallipolis Lock in accordance with the above referenced contract.

If you have any questions regarding my analysis of the pumping test made on this system, I shall be glad to answer them.

Sincerely,

Charles Mansur Consultant

Sharly Manun

ANALYSIS OF PUMPING TEST ON PREDRAINAGE WELL SYSTEM FOR GALLIPOUS LOCK

INTRODUCTION

In order to facilitate digging the excavation for construction of the second Gallipolis Lock, a slurry cutoff wall was constructed around the top of the excavation, through the alluvial sands stratum at the site. Thirty six wells were also installed with the area of the excavation to pump out the groundwater trapped within the cutoff wall. A number of piezometers were installed inside and outside the wall for checking the efficiency of the cutoff and predrainage system. The locations of the cutoff wall, predrainage wells, and the piezometers are shown on Plates 1 and 2.

The specifications for this work required that a full scale pumping test be made on the predrainage well system after installation of the slurry wall and the well system were complete. The cutoff wall was completed on 17 July 1988 except for 40 ft at its connection with the downstream guidewall for the existing lock (see Plate 1). This opening in the cutoff wall was still open at the time the pumping test was made. All the predrainage wells have been installed by the time the pumping test was made but Wells 22 and 23 had been removed by the Contractor because of interference with his excavation before the test was made.

The piezometers shown on Plate 1 had been installed but Piezometers 6 and 7 had been removed by the Contractor prior to start of the pumping test. Piezs 4 and 10 were located adjacent to Wells 18 and 29, and were not included in this study. The groundwater table (GWT) at Piez 8 was plotted on Plate 4 but the readings were not included in averaging the piezometric test data because of the apparent inconsistent readings of Piez 8 during the test. Although the pumping test on the predrainage system was supposed to have been made prior to the start of any excavation or before any individual wells were pumped, some of the predrainage wells (#1, 2, 3, 4, 5, 6, 7, and 8) were being pumped by the Contractor as the test began on 25 Aug 1988. [Pumping a few of the wells may have been started prior to complete closure of the cutoff wall.]

BASIC PUMPING TEST DATA

Basic groundwater and pumping test data are summarized in the following tabulation.

Completion of cutoff around excavation	17. July 1988
Start of pumping some wells	In June or prior to closure of cutoff
Average groundwater level within excavation on 16 June 1988	530.3 mcl

Average groundwater level within excavation on 25 October 1988	504.5 msl
Predrainage wells installed	36
Predrainage wells removed (#22 and #23) by Contractor prior to start of pumping test	2
Wells in downstream end of lock area pumped prior to start of pumping test	#1 - #8
Number of wells pumped during pumping test	34
Start of pumping test	:00 pm 25 Aug 1988
Completion of specified pumping test	00 pm 27 Aug 1988
Duration of specified pumping test	48 hours
Total pumping time after 25 Aug 1988	60 days
Observation of piezometers continued for 60 days after start of test	25 Oct 1988
Approximate maximum capacity of pumps in wells	300 gpm
Average rate of pumping on 8:00 pm 25 Aug 1988	275 gpm/well
Average rate of pumping on 7:00 pm 27 Aug 1988	227 gpm
Upper pool elevation at start of pumping test	539.3 msl
Lower pool elevation at start of pumping test	516.6 msi
Fall in pool levels during August pumping test	0.3 ft
After completion of pumping test, Upper and Lower pools rose	0.5 ft
Average groundwater level in excavation at start of pumping test	521.0 msl
Average drawdown in excavation (Piezometers 2, 3, 5, 9, & 11)	
During 48-hr pumping test During 100 hrs of pumping During 280 hrs of pumping From start of pumping to 25 Oct 1988 Effective days of pumping with all 34 wells pumping	3.75 ft 6.40 ft 17.1 ft 25.8 ft 63.5 days
Specific yield of sand formation being drained based on 100 hours of pumping at an average pumping rate of 230 gpm	18%

11- I-16

Plans of the predrainage wells and piezometers used in the pumping test are shown on Plates 1 and 2. The GWT at each of the piezometers at the following dates and times on Plate 1:

16 June 1988 prior to closure of the cutoff 25 October 1988 (after 60 days of pumping all wells)

B

ANALYSIS OF PUMPING TEST DATA

The piezometric data plotted in plan on Plate 1 show that the GWT on 6/16/88 inside of the lock area sloped from about El 533 at the upstream end of the lock area to about El 525 at the downstream end of the lock area. The GWT outside of the cutoff wall sloped from about El 538 (slightly below the upper river pool) at the upstream end of the area to about El 519 (slightly above the lower pool) at the downstream end of the lock area. [This is about as might be expected with an upper pool level of El 539 and a lower pool level of El 517.] Once the cutoff wall around the lock area as closed, the GWT inside of the lock area leveled out to a certain extent.

As a result of pumping predrainage Wells 1, 2, 3, 4, 5, 6, 7, and 8 at the downstream end of the lock area, the average GWT inside of the lock area had been lowered from El 534 to 527 (or about 7 ft) at the upstream end of the lock area and from El 525 to 515 (or about 10 ft) in the downstream end of the lock area, prior to start of the pumping test.

The GWT outside of the lock area (immediately) prior to start of the pumping tests is shown by an asterisk(*) for the various piezometers on Plate 1. During the pumping period, the GWT was lowered 9 to 10 ft at the upstream end of the lock area, 5 to 6 ft at the center, and 6 to 7 ft at the downstream end of the lock.

The average drawdown (DD) of the GWT at Piezs 2, 3, 5, 9, and 11 within the lock area are plotted vs Elapsed Pumping Time (T) on Plate 3.

As Piezs 2, 3, 5, 9, and 11 all exhibited similar drawdown characteristics, only these piezometers were averaged to plot the average DD curve on Plate 3. Piez 1 first seemed to be inoperative and was not included with the plotted data. Why Piez 8 behaved so differently than the other piezometers in the lock area is not known; however, the more rapid DD in Piez 8 can probably be attributed to its being located near the downstream wing wall and where there was a smaller zone of water to be pumped out by the predrainage wells along the downstream lock walls.

Pumping 34 predrainage wells for 110 hrs, or approximately 4-1/2 days, lowered the water level in the lock area an average of 7.0 ft (see Plate 3). The average rate of pumping Q_w at the

start of the pumping test (8:00 pm 8/25/88) was 275 gpm; after pumping for 48 hours, the rate of pumping had diminished to 227 gpm.

The average groundwater level in the lock area had been lowered approximately 9 ft by the Contractor pumping Wells 1 through 8 prior to start of the pumping test. This previous drawdown of 9 ft was added to the DD's obtained during the pumping test and then the total DD plotted vs Elapsed Pumping Time on Plate 5, the basic graph of which was copied from Plate 11 in the Charles Mansur report: Study of Dewatering Excavation-Gallipolis Locks and Dam Replacement - Ohio River dated 7 Oct 1983. When allowance is made for the capacity of the pumps being a maximum of 300 gpm rather than the 600 gpm rate used in computing the graphs on Plate 5, it appears that the predrainage wells and pumping system is performing about as expected.

The Upper and Lower river stages during and after the pumping test are plotted on Plate 4 until 25 Oct 1988. The readings of all operative piezometers both outside of the cutoff wall and the landside wall of the existing lock are also plotted from 16 June 1988 to 25 Oct 1988. Although the pool levels fell about 0.3 ft during the pumping test, both the Upper and Lower pools rose gradually about 0.5 ft after September 1.

After the cutoff wall was closed and pumping the predrainage well system was started, the GWT outside of the cutoff wall fell varying amounts by Oct 25 as shown in the following tabulation:

_	Fall of GWT Outside of Cutoff								
	Piezometer	From Aug 25 to Oct 25	From June 16 to Oct 25						
	12	0.6 ft	0.6+ ft						
	13	0.6	0.6+						
	14	0.4	4.0						
	15	1.0	1.8						
	16	2.3	2.6						
	17	1.1	1.1+						

As both the Upper and Lower pools were relatively stable, or rising slightly during most of the above periods, the fall in the GWT outside of the cutoff as the groundwater level was lowered inside, there must have been some leakage through the slurry wall and/or through the underlying rock into the area being dewatered. Such leakage would also have prevented the GWT inside of the cutoff wall from being lowered as fast as otherwise would have occurred.

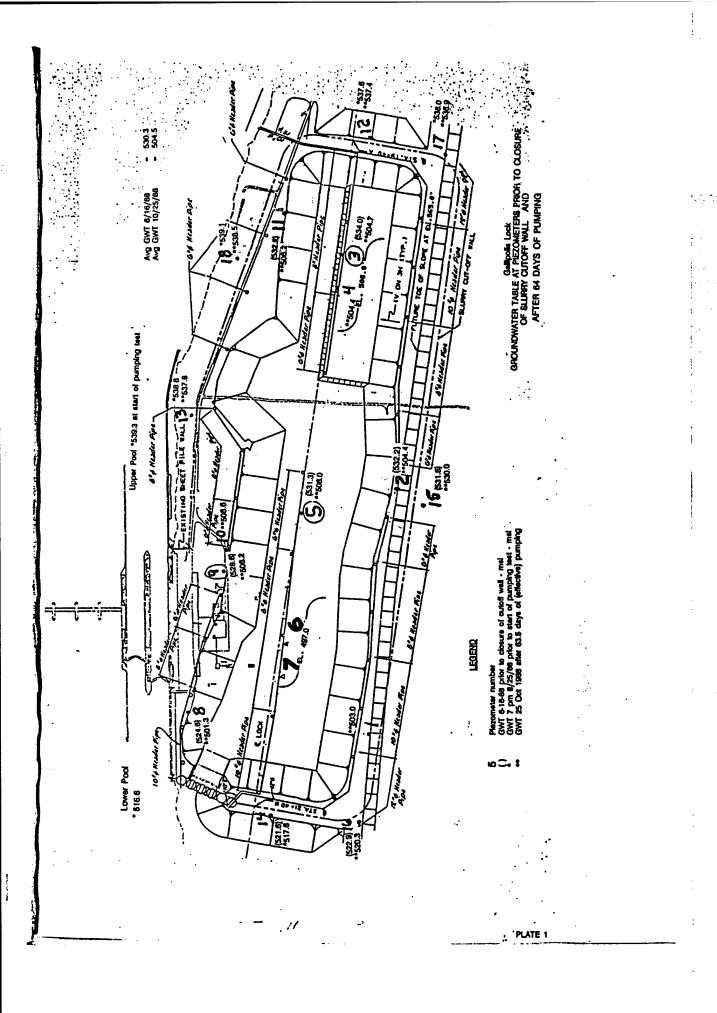

Regardless of whatever leakage there was through or beneath the cutoff wall, pumping the 34 predrainage wells lowered the groundwater therein about 26 ft during about 60 days of pumping,

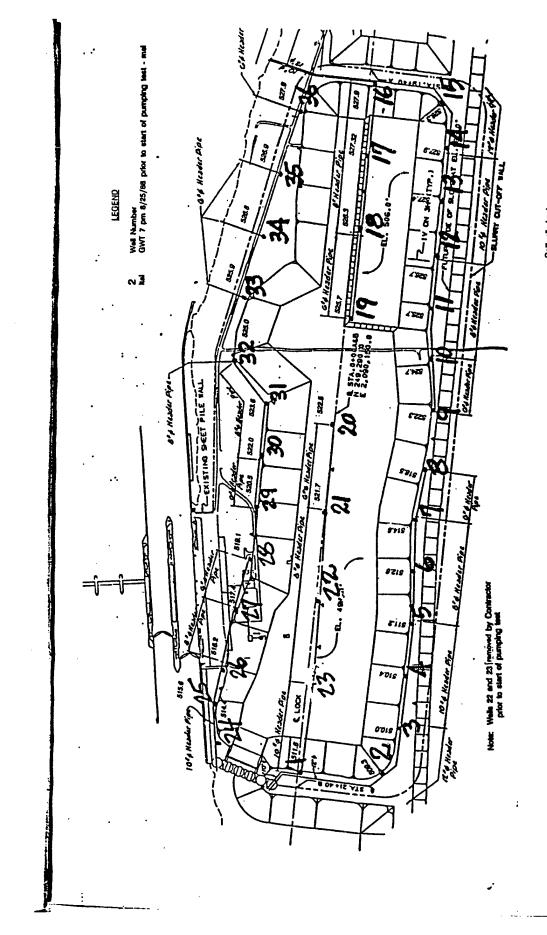

or within about 3 ft of the drawdown calculated (see Plate 5). Had 600-gpm pumps been used, as assumed in the theoretical calculations, rather than 300-gpm, and had there been no seepage through or under the cutoff, the check between calculated and actual drawdowns would have been better. In any event, the cutoff well and predrainage system have worked basically as planned.

TOTAL NONELECTRIC
SEQUENTIAL BLAST INITIATION
FOR USE IN ALL SURFACE
BLASTING APPLICATIONS

A NONELECTRIC DELAY SYSTEM SUITED FOR SURFACE COAL MINING, QUARRIES, OPEN PIT MINES AND CONSTRUCTION The Total Nonel® System serves as an excellent surface trunkline and downline initiation system for the following reasons:

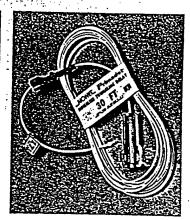

Safe Factory assembly of Nonel components is safer than field cutting and splicing of initiation components. Nonel tube can not be initiated by high frequency radio transmissions, static or stray electrical energy, flame, friction, or impact found in normal mining conditions. However, blasting caps are far more sensitive to these conditions.

Simple-Flexible Nonel components, both the NTD and the LLHD Nonel Primadets®, are factory assembled. They can be readily and simply connected to accommodate both basic and complex blast initiation patterns without complex circuitry.

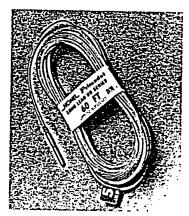

Non-electric Requires no knowledge of electric circuitry. Completely non-electric—no need to instruct blasters on intricacies of electric circuits. No need for elaborate training and retraining of blasters. This is the simplest system available for applications requiring unlimited sequential delays.

Noiseless The Nonel initiation system is quiet. The signal moving through an initiated tube is so quiet that it can be called Noiseless.

Economical The Nonel system allows for a reduced inventory resulting from the elimination of stocking various lengths of a complete delay series.

NOISELESS TRUNKLINE DELAY

LONG LEAD H.D. NONEL PRIMADET

DESCRIPTION OF SYSTEM
COMPONENTS
Nonel Primadets are nonelectric blasting caps using Nonel tube as a lead.

NTD units with Bunch Blocks and LLHD Nonels are Nonel Primadets whose lengths, delay times and hardware are suited for use as trunklines and downlines to inhole delays for surface blasting. The NTD and LLHD units are factory assembled with 5 and 3 components respectfully.

NOISELESS TRUNKLINE DELAYS WITH BUNCH BLOCKS

LONG LEAD HD NONEL PRIMADETS

Both the NTD and LLHD Nonel Primadets incorporate the Nonel tube which transmits a noiseless initiation signal from the initiation end to the delay in the output end. Reactive material on the inside of the tube propagates at 6000 feet per second.

The blasting cap has an integral millisecond (MS) delay element which initiates LLHD downlines and outgoing NTD's.

The blasting cap has an integral millisecond delay element. The cap will initiate all commercially available cast boosters and other cap sensitive explosives.

A delay tag indicates the millisecond end to end delay time. The tag is located just below the water tight ultrasonic seal at the end of the Nonel tube.

The Bunch Block connector is made of durable plastic and is designed to hook up LLHD downlines and outgoing NTD's.

LLHD Nonel Primadets utilize the same Nonel tube used for NTD's, however they have an added amount of abrasion resistant plastic. Tensile strength is also increased by this additional plastic. The LLHD tube has adequate physical properties to be used in all mining environments.

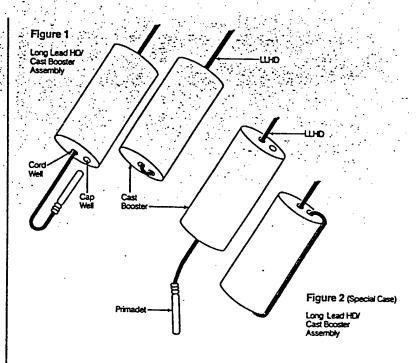

"J" Hook", an inert moveable fitting at the initiation end of the NTD for quick reliable connection to Primacord downlines.

*NOTE: The "J" Hook is used only when the NTD is to be initiated by Primacord. See separate bulletin on Noiseless Trunkline Delays. Nonel will not initiate another Nonel Line through a "J" Hook.

PRIMER ASSEMBLIES

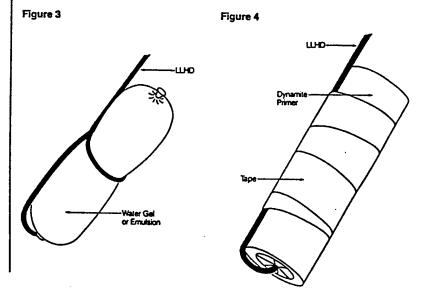

In all cases the LLHD Nonel Primadet of appropriate delay period is inserted into a booster. Any cap sensitive booster can be used as the Nonel tube emits virtually no side energy. The primer on the top of the explosive column would be assembled as shown in Figure 1.

Cast boosters initiated with a blasting cap provide more energy from the end opposite the cap well due to the position of the cap and slight mass difference of the cast explosive on that end. The primer on the bottom of the column would be assembled as shown in Figure 2.

With a soft package booster, the Nonel lead can be half-hitched or taped around the cartridge with the Primadet inserted fully into the base of the booster (Figure 3).

When using paper cartridge boosters, it is best to tape the Nonel lead to the booster so if the assembly needs to be pulled from the hole, it will not hang up (Figure 4).

LOADING PROCEDURES

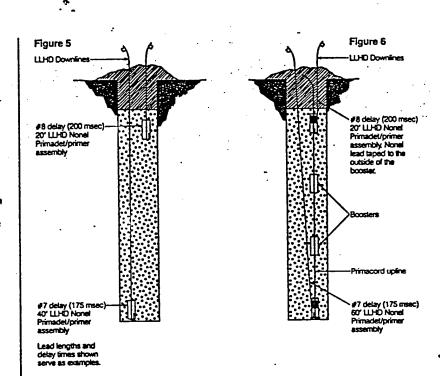

SOLID COLUMN LOADED HOLES

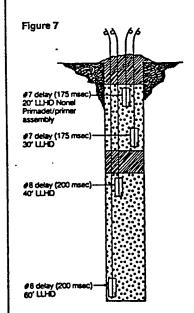

- An LLHD Nonel Primadet/primer assembly is lowered into the borehole and the end of the Nonel tube is secured at the collar.
- Explosive material is loaded into the borehole.
- A second LLHD primer assembly is lowered to the top of the explosive column.

A Primacord upline may be used when loading wet bag material. Place the Nonel Primadet into the cap well of the primer; tape the Nonel tube to the outside of the primer; and run the upline through the primer as shown in Figure 6.

DECK LOADED HOLES

- An LLHD Nonel Primadet/primer assembly is lowered into the borehole and the end of the Nonel tube is secured at the collar.
- 2. The explosive material is loaded into the borehole.
- If the bottom charge is to be double primed, then a second LLHD Nonel Primadet/primer assembly of the same delay is lowered to the top of the explosive charge.
- Stemming material for decking is loaded.
- The above procedure is then repeated until the appropriate amount of decks are completed.

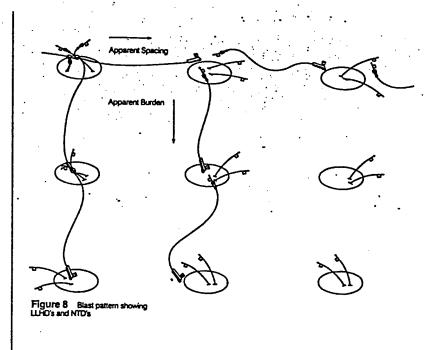

HOOKING UP THE SYSTEM

DELAY JUNCTION

The system in its simplest form has one or two LLHD Nonel Primadets down the hole, and one incoming and one or two outgoing NTD's (Figure 8).

e two Nonel tube ends of the outgoing NTD's and the two LLHD Nonel tube ends are placed into the Bunch Block (Figure 10). After the four outgoing Nonel tubes have been placed against the blasting cap in the Bunch Block snap the lid of the block closed (Figure 11).

When the hook-up is complete, place the assembly on the ground so the outgoing NTD tubes do not double back over or near the block. Cover the assembly with stemming material to minimize the noise from the blasting cap and to insure that the outgoing NTD tubes are not close enough to the Bunch Block to cause the tube to be damaged or cut off prior to initiation.

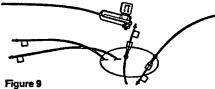

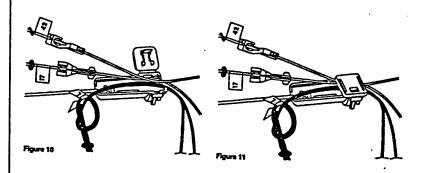

Figure 9 Note: The "J" Hook has no function in an all Nonel hook-up.

APPLICATIONS - DELAY PATTERNS

The Nonel System is best suited for those applications which require more delay intervals due to vibration limitations and cannot have detonating cord trunklines because of overpressure (air blast) restrictions. It is common to design blasts requiring 100 or more separate charges to be detonated with no less than 8 milliseconds between the charges. LLHD Nonel Primadets provide an unlimited number of constant, precise delay intervals when used with Nonel NTD's.

SEPARATE CHARGE FIRING— SAME DELAY EACH HOLE

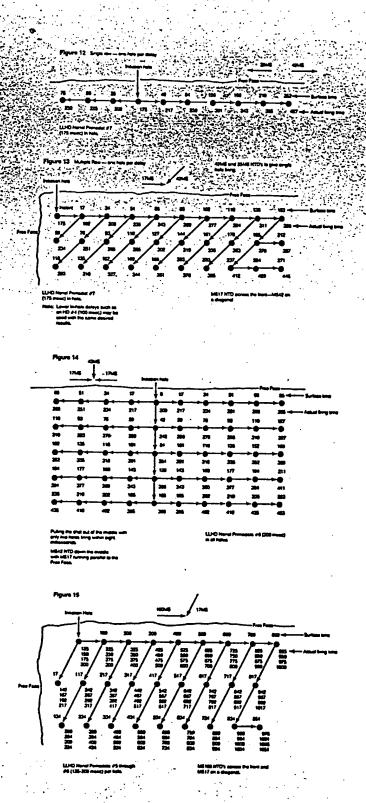

A blast consisting of a single charge per hole normally has the same LLHD Nonel Primadet delay period in every hole. In some cases, the next higher delay period may be placed at the top of the column charge. Surface delay combinations of MS42 or MS25 and MS17 NTD's as shown by Figures 12 and 13 provide for two important inctions:

- The actual detonation time of the blasthole is greater than the surface activation time. Therefore, the risk of cutoff downlines or trunklines due to ground movement is minimized.
- Blastholes detonate with a minimum of an 8 millisecond interval.
 An unlimited number of delays can be created with the proper selection of surface delay times and patterns.

VIBRATION CONTROL

In Figure 15 an echelon pattern is shown using 100MS NTD's across the front with 17MS on a diagonal. There are 4 decks shown per hole without duplicating inside 8 milliseconds for 3 rows. Up to 8 decks can be fired maintaining 8 millisecond minimum interval in a Three Row Pattern. To determine the surface delay across the front to accommodate a specific number of deck charges simply multiply the desired number of decks times 25MS.

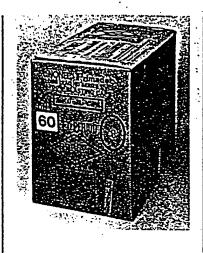

or example: six separate charged Jecks would require 6 × 25MS or 150MS minimum across the front. Always use 17MS NTD's straight back or on the diagonal (Figure 15).

INITIATING THE NOISELESS TRUNKLINE SYSTEM

The primary initiating devices for the trunkline are (1) Nonel Noiseless Leadin Lines, (2) electric blasting caps, and (3) cap and safety fuse assembles. Never attach a blasting cap for the purpose of initiating a blast until everything and everybody are in a safe

Make the primary initiating device, attachment the very last step in readying the blast. Attachment of the primary initiating device should be made to the first hole to fire in the blast. This hole fires which in turn fires outgoing noiseless trunklines.

DISCLAIMERS

ATTENTION

The information and recommendations described in this bulletin cannot possibly cover every application of the product or variation of conditions under which the product is used. The recommendations herein are based on the manufacturer's experiences, research, and testing. They are believed to be accurate, but no warranties are made, expressed or implied. Also, the specifications contained herein are all nominals which represent our current production. The product described may be subject to change. Please feel free to contact the Ensign-Bickford Company for verifications.

NO WARRANTIES OR LIABILITIES

The product described herein is sold "as is" and without any warranty or guarantee, express or implied, arising by law or otherwise, including without limitation any warranty of merchantability or fitness for any purpose. Buyer and user agree further to release and discharge seller from any and all liabilities whatsoever arising out of the purchase or use of any product described herein whether or not such liability is occasioned by seller's negligence or based upon strict products liability or upon principles of indemnity or contribution.

Nonel Primadets are manufactured under U.S. Patent #3,590,739, U.S. Patent #3,125,024 and other patents pending.

LINE DRILLING

Line drilling will conform to section 2F-12.4 of the Contract Documents. Line drilling will be performed for all vertical faces against which concrete for sills, port deflectors and lateral walls will be placed and for all stepdown areas where adjacent foundation surfaces for concrete structures are lateral different elevations.

GENERAL DESIGN

General line drilling techniques will adhere to the procedures set forth in the publication "Four Major Methods of Controlled Blasting" by the Dupont Company, Inc. This brochure is referenced in the Contract Documents and a copy is enclosed for your reference.

LINE DRILLING

Principle

Line Drilling involves a single row of closely spaced, unloaded, small-diameter holes along the neat excavation line. This provides a plane of weakness to which the primary blast can break. It also causes some of the shock waves created by the blast to be reflected which reduces shattering and stressing of finished wall.

lication

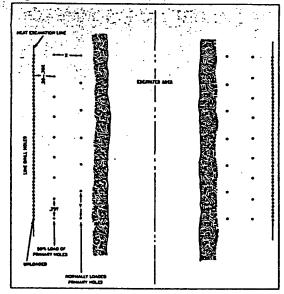

Line drill holes are generally 2 to 3" in diameter and are spaced from 2 to 4 times the hole diameter apart along the excavation line. Holes larger than 3" are seldom used in line drilling since the higher drilling costs cannot be offset by increased spacings.

The depth of line drill holes is dependent upon how accurately the alignment of the holes can be maintained. To get good results, the holes must be on the same plane; any wander or drift by attempting to drill too deep will have an adverse effect on results. For holes of 2 to 3" diameter, depths greater than 30 ft. are seldom satisfactory.

The blast holes directly adjacent to the line drill holes are generally loaded lighter and are more closely spaced than the other holes. The distance between the line drill holes and the directly adjacent blast holes is usually 50 to 75% of the normal burden. A common practice is to reduce the spacings of the adjacent blast holes the same amount with a 50% reduction in explosives load. The explosives should be well distributed in the hole using decks and Primacord* downlines.

Best results with line drilling are obtained in homogeneous formations where bedding planes, joints and seams are at a minimum. These irreguities are natural planes of weakness that tend to note shear through the line drilled holes into finished wall. Therefore, thin-bedded sedimentary and more unconsolidated metamorphic formations are not well suited to line drilling for overbreak

Figure 1.

TYPICAL PATTERN AND PROCEDURE FOR LINE DRILLING

control unless drilling can be done perpendicular to the strike of the formation. This, however, is not practical in most excavation work.

Open Work—Figure 1 shows a typical pattern and procedure for line drilling in open work. Best results are obtained when the primary excavation is removed to within 1 to 3 rows of the neat excavation line. The last row or rows of holes are then slabbed away from the line drill holes using delay caps or "Primacord" Connectors. This procedure gives maximum relief in front of the finished wall, allowing the rock to move forward thus creating less back pressure which could cause overbreak beyond the line drilling.

'n thin-bedded sedimentary and unconsolidated tamorphic formations, results with line drilling an usually be improved by light loading some of the line drill holes. This procedure led to the development of Cushion Blasting and Smooth Blasting. Also, it was found that line drilling results could be improved in some formations by light loading and firing the line drill holes in advance of the primary blast, and this led to the introduction of the technique known as Pre-Shearing or Pre-Splitting These modifications of line drilling all promoted additional weakness along the neat excavation line by using explosive force to shear the rock between the holes

Underground Work—The application of basic line drilling employing only unloaded holes is very limited in underground work. Generally closely spaced holes are employed but light loads are used. This is the technique we prefer to call Smooth Blasting and it will be described later.

Advantages

Line drilling is applicable in areas where even the light explosive loads associated with other controlled blasting techniques may cause damage beyond the excavation limit.

When used with other controlled blasting techniques, line drilling between the loaded holes promotes shearing to improve results

Limitations

There are a number of limitations of line drilling

which must be recognized:

Line drilling is rather unpredictable except in the

most homogeneous formations.

Due to the close spacings required, drilling costs

are high

Because line drilling requires a large number of holes on rather close spacings, drilling becomes tedious and results are often unsatisfactory due to poor hole alignment.

IRESPLIT ** Perimeter Blasting Products

(IRESPLIT D was previously termed HERCOSPLIT WR; IRESPLIT S was previously termed IREMITE 60 continuous.)

IRESPLIT products are highly water-resistant explosives designed for open pit or underground blasting operations where precision overbreak control is desired. When used with presplitting or perimeter (smoothwall) blasting techniques, IRESPLIT produces straight-lined, smooth-faced walls in reasonably homogeneous rock formations.

· Advantages

Product Variety. IRECO offers both IRESPLIT S, a gelled slurry on a continuous spool, and IRESPLIT D, a semigelatin dynamite in 24-inch cartridges.

Minimized Rock Overbreak. Rock overbreak behind the IRESPLIT blastholes is minimized. Less extra unpaid-for excavation and extra concrete are required because excess backbreak is eliminated.

IRECO Incorporated

Priming and Loading

IRESPLIT D. The paper sleeve connector enables coupling of each IRESPLIT D cartridge into a continuous explosive. The column is lowered into the borehole by the detonating cord downline. The detonating cord is commonly half-hitched or taped tightly around the first cartridge in the borehole. At approximately six-foot intervals, the detonating cord should be secured to the column of explosive so it remains in close contact to ensure propagation of the entire column. IRESPLIT D can withstand 50 feet of water pressure up to nine hours.

IRESPLIT S. IRESPLIT S should be used at 10°F or higher and primed with a minimum 40 grain detonating cord secured to the entire length. Water depth is limited to 25 feet with IRESPLIT S.

Transportation, Storage and Handling

IRESPLIT has a D.O.T. Classification of High Explosive, Class A.

Transport, store and handle IRESPLIT in compliance with federal, state and local laws

Product Disclaimer

IRECO disclaims any warranties with respect to this product, the safety or suitability thereof, or the results obtained, whether express or implied, INCLUDING WITHOUT LIMITATION, ANY IMPLIED WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE AND/OR ANY OTHER WARRANTY. Buyers and users assume all risk, responsibility and liability whatsoever from any and all injuries (including death), losses, or damages to persons or property arising from the use of this product. Under no circumstances shall IRECO be liable for special, consequential or incidental damages.

RX and RX Plus Bulk Repumpable Emulsions and ANFO Blends

RX and RX Plus are Bulk Repumpable Emulsion Blasting Agents, which can be used straight or in combinations with up to 30% ANFO. The ANFO containing blends are manufactured in the IRECO RP trucks which have an 11,000 pound capacity tank for the Repumpable Emulsion and a 5,000 pound capacity for pre-mixed ANFO. The two ingredients are mixed, and pumped through a hose into the borehole. Quarrying and construction work are the principle applications for RX and RX Plus:

Advantages

Excellent Detonation Properties. RX and RX Plus with ANFO blends offer a variety of detonation velocities, bulk strengths and all have high gas volumes which combine to give excellent results in nearly all rock formations.

Bulk Explosives Storage. The IREGEL REPUMPABLE BULK SYSTEM helps save time and money for mine operators, quarry operators and contractors because it alleviates many explosive storage and handling problems.

Customer Operated. RX and RX Plus are logical additions to operations with existing ANFO capabilities. IRECO will provide the equipment, training and technical support necessary to make the system easily operational by customers.

High Loading Density. RX and RX Plus Repumpable Explosives and ANFO blends have high borehole loading densities and complete borehole coupling, which result in improved fragmentation and pattern expansion.

IRECO Incorporated

Characteristics

Detonating Cord Downlines not Recommended

Double or multiple priming recommended in 20' or longer powder columns.

Generally recommended for open pit use however RX and RX Plus can be formulated for underground applications. Consult your IRECO representative.

Transportation, Storage, and Handling

The RX and RX Plus emulsion component can be stored for one month at temperatures between 0°F and 90°F (-17°C and 32°C).

Transport, store and handle RX and RX Plus in compliance with Federal, state and local laws governing bulk Blasting Agents.

BLASTEX

Packaged Emulsion Blasting A

BLASTEX is a product line of economical blasting agents specifically formulated with packaged diameters as small as two inches. BLASTEX 100 and 120 are re BLASTEX 80 has an IME Class 1 Fume Rating for underground use.

Advantages :-

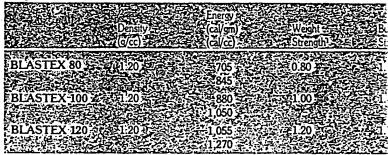

Firm Packages. Firm packages provide easy handling loading.

Not a Class A Explosive. BLASTEX does not require loass A High Explosive.

Water Resistant. BLASTEX has excellent water resistance, even when the packages provide easy handling loading.

Energy Levels. BLASTEX has high velocity and pressure and comes in three e

Properties

The minimum recommended booster for all BLASTEX Emulsion Slurries is a : Detonating cord downlines are not recommended in boreholes of less than 4 inc Dynamite is not recommended as a booster for BLASTEX.

IREMITE EMULSION Small Diameter Explosives

IREMITE EMULSION is a cap sensitive, packaged slurry explosive used in dry and wet boreholes. IREMITE 42, 62 and 82 are oxygen balanced for underground applications.

Advantages 🐇

Loading and Tamping. The rigid consistency of IREMITE EMULSION permits easy handling and rapid loading.

The products have good tamping characteristics which produce high borehole loading densities.

Furnes. Rapid re-entry into a blast site is permitted after an IREMITE EMULSION blast. The detonation products are low in noxious gases and smoke.

Non-Headache. The powder headache, which diminishes work efficiency by causing discomfort, is eliminated with IREMITE EMULSION.

Water Resistance. IREMITE EMULSION retains its design characteristics while in wet holes for long time-periods, even when the packages are broken.

Low Temperature Sensitivity. IREMITE EMULSION remains cap sensitive down to 10°F.

Under no circumstances shall IRECO be liable for special, consequential or incidental damages.

UNIGEL[®] Semigelatin Dynamite

UNIGEL is specifically developed for all purpose blasting applications, including underground and surface mining. It replaces more expensive specialty grade dynamites that offer varying energy values with each grade. UNIGEL has excellent uniformity of mixture and plasticity, will detonate completely under moderate water pressure, and is an excellent primer for ANFO.

Advantages

Universal Blasting Applications. UNIGEL is a single explosive grade for universal blasting applications, which simplifies inventory requirements.

Fumes. Afterblast fumes and smoke are at a minimum.

Cost-Saving. UNIGEL provides excellent performance for less cost per cubic yard.

Trenching Explosive

A new IRECO packaged emulsion especially designed for trenching and utility work

Advantages

Resistant to Dead Pressing

IREMITE TX can be used in boreholes as close together as 2.5 feet and shot with any delay sequence ranging from 25 milliseconds to several seconds without loss of sensitivity from detonation of charges in adjacent boreholes.

Non-Headache

The powder headache, which diminishes work efficiency by causing discomfort, is eliminated with IREMITE TX.

Water Resistance

IREMITE TX retains its design characteristics while in wet holes for long time period, even when the packages are broken.

Low Temperature Sensitivity

IREMITE TX remains cap sensitive down to 0°F.

GLR CONSTRUCTORS

OVERVIEW OF VIERA-TECH ENGINEERS, INC.

Vibra-Tech Engineers, Inc. engages in consulting in the area of Liability Seismology. With eighteen offices nationwide, we have served the construction, quarry, mining, and other explosives using and seismic related industries throughout the United States, Canada, Central America, and the Carribean.

EXPERIENCE RECORD AND EXPERTISE

Since our beginning, the major endeavor of Vibra-Tech has been to serve as a liability protection organization to users of explosives and vibration producing equipment. We are the largest organization in the United States so dedicated. Vibra-Tech was an early pioneer in the continuing development and improvement of many of the techniques and most of the instrumentation presently used in the areas of loss control and liability seismology in conjunction with mining, quarring, construction and demolition activities.

We provide liability protection primarily through five general categories of services.

- 1. Pre-Blast/Construction Surveys of buildings, wells and other structures, to document their condition. Vibra-Tech has conducted hundreds of thousands of these surveys.
- 2. The use of specialized portable seismographs and air effects recorders, much of which has been designed by and proprietary to Vibra-Tech. The data from these instruments are analyzed for comparison to recognized standards for structure protection.
- 3. Public relations efforts, either in the form of public meetings, or in conjuntion with pre-blast/construction surveys. We consider our efforts in educating and assuring building owners that their properties will be protected to be a very important part of our loss-control program.
- 4. Damage claim Investigations, usually conducted on behalf of insurance carriers, to determine the validity of damages claimed by property owners.

5. Expert witness testimony during civil litigations involving alleged property damages. Vibra-Tech has participated in thousands of litigations in this capacity.

Other areas of expertise include:

Noise Surveys for the purpose of evaluating noise effects on individuals under varying conditions with respect to the source, receiver, and transmission medium.

Seismographic and Noise Equipment Design and Testing in conjunction with various major manufacturers.

Design of Vibration and Noise Specifications for construction projects under the direction of such organizations as the AEC, electric and water utilities, and major engineering and contracting firms.

Development of Vibration and Noise Legislation conjointly with the authorities of the states of Pennsylvania, Kentucky, Illinois, Indiana, West Virginia, Georgia, New Jersey, and Maryland.

Geophysical and Geohydrological Studies to determine geologic and ground water conditions in conjunction with construction, mining, and fill projects.

Blast Design Engineering to provide optimum blasting parameters for efficient rock excavation while minimizing deleterious effects.

Our services are explained further in the enclosed brochures.

A listing of our clients and/or projects with which we have been involved will be furnished upon request. A partial list can be found in the enclosed material.

PERSONNEL QUALIFICATIONS

The following representatives of Vibra-Tech Engineers, Inc. will have responsibilities as required in conjunction with this project.

Mark R. Trimble, B.S. Geology, California University of Pennsylvania. Additional studies at Midland College and Permian Basin Graduate Center, both in Midland, Texas. Area Manager at Charleston, WV office and Geologist/Vibration Consultant. Since 1984, experienced in vibration recording and analysis, pre-job surveys, damage claim evaluation for structural and water supply claims, expert witness testimony. Prior to 1984 and since 1981, was Operation Engineer and Administrator for Western United States with Geophysical Service, Inc. Licensed and certified blaster in state of West Virginia. Certified instructor for West Virginia Blaster Certification Program. Memberships include: Society of Explosives Engineers, Association of Ground Water Scientists and Engineers, West Virginia Mining and Reclamation Association, Contractors Association of West Virginia.

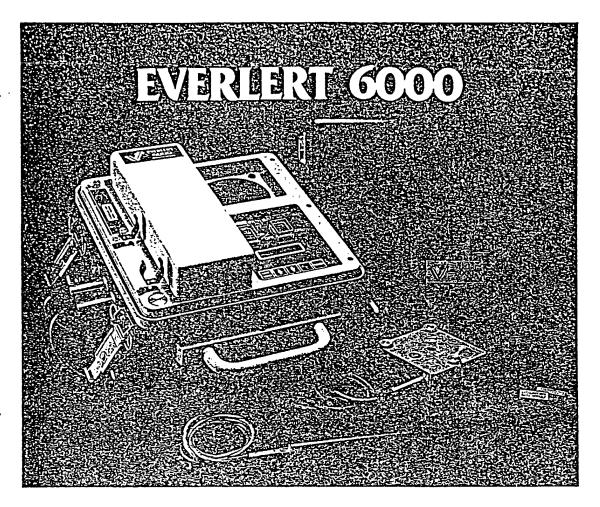

Thomas W. Novotny, B.S. Geophysics, Bowling Green State University. Graduate Geophysical Studies, Pennsylvania State University. Licensed blaster - Commonwealth of Pennsylvania. Member of SME and AIME. Vice-President of Vibra-Tech Engineers, Inc. and Regional Manager at Pittsburgh, PA office. Previous experience in manufacture of electronic equipment for a major aerospace firm. Employed by Vibra-Tech Engineers, Inc. since 1970. Experience in recording and analysis of ground and air motion resulting from industrial sources, building inspections, damage claim investigations, expert witness, hydrogeologic studies and ground water quality analysis.

Anthony J. Petro, B.S. Electrical Engineering, Brown University, P.E. (Pennsylvania, New York, New Jersy, Massachusetts, Connecticut, Maryland, Illinois, Tennessee, Georgia, Kentucky, Nest Virginia, District of Columbia, And Florida). President of Vibra-Tech Engineers, Inc. Member of Blaster Advisory Committee, Commonwealth of Pennsylvania. Experienced in manufacture and use of electrical-electronic devices and measuring instruments. Employed by Vibra-Tech Engineers, Inc. since 1956. Experienced in vibration and sound measurment and blast effects.

If other Vibra-Tech personnel are required to perform on this project at some time in the future, their resumes will be furnished upon request.

EQUIPMENT QUALIFICATIONS

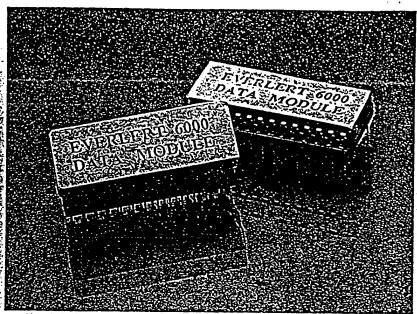

The equipment proposed for this project meets all requirements st forth in the specifications written by the Corps of Engineers. A complete description of the instrumentation is given in the enclosed literature.

A Digital Seismograph for Recording Ground Vibration and Air Concussion.

- Exclusive Plug-In Data Module provides tamper-proof, permanent storage of all data for legal credibility and liability protection.
- Complete Record Analysis available from DATA MODULES for Structural Response (RSVP) and complete frequency information.
- Low Cost Record Verification for compliance with regulations or specification requirements.
- Solid-State Components give maximum reliability under adverse field conditions.
- Simple Operation achieved with 2-buttons, a 4-key membrane and LCD step-by-step instructions.

- Unattended Operation provided by internal batteries and controllable triggering by seismic and/or air events.
- Automatic Calibration, Range Selection and Event Identification insure proper and accurate operation.
- Immediate Results Available from LCD readout, including recall of previous events recorded.
- Optional Built-In Printer Available for printing full analog waveform with peak values, dominant frequencies via Fourier analysis and maximum resultant values.

Exclusive solid state data module provides for permanent storage of complete ground vibration and air overpressure information.

SCOPE

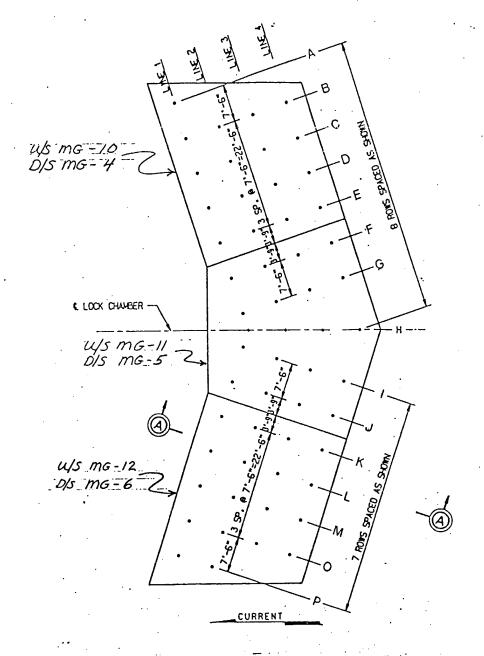

This procedure covers all operations in connection with the drilling, installation of resin cartridges, anchor bars and prestressing operations as specified by Contract Specification Section 20. The areas of work are limited to the four (4) miter gate sills, main lock up stream and down stream and auxiliary lock up stream and down stream at construction joint (CJ) elevation 488.0.

All procedure are based on the requirements of contract specifications, published product information and standard construction practices. Due to the inherent properties of the resin anchors, time and temperature factors are prime considerations.

Unknown factors may include sub-surface defects such as voids, clay seams, flowing water, or unstable holes. Defects of this nature must be referred to the Corps of Engineers for their determination.

SECTION A-A

MITER GATE SILL ANCHORAGE

DRILLING PROCEDURES

Drilling equipment will be the same John Henry drill as used for blast hole drilling. Drill will be adapted by manufacture to accommodate 1 1/4 inch drill steel.

Drilling will be observed by GLR Q.C. personnel (see drilling log). Drill hole will be air blown clear with drilling equipment or separate air cleaning if required. Drill holes will be covered or plugged to prevent intrusion of foreign material into drill hole.

Any large irregularities in concrete surface (over 1/2 inch) shall be leveled with dry pack grout (Dayton Superior - sure grip high performance) minimum 24 hour cure prior to anchor installation.

ANCHOR DETAIL Rev / 10

ANCHOR BAR INSTALLATION

Prior to anchor bar installation the drill hole will have been loaded with Faslok-T cartridges, base plate grouted in place and prestressive quipment will be ready for immediate use.

<u>CAUTION</u> - This operation will commence timed event shown by clock symbol

Elapsed time = minutes

- Chuck anchor rod with drive adaptor into drill, "Untimed" position over hole in plumb position
- Feed anchor rod to top of Faslock-T cartridges "Untimed"
- Rotate slowly and feed anchor bar through cartridges until full depth of 24 feet is reached. (Rotation Optional)

Elapsed time = \emptyset -3 minutes

4. Rotate anchor bar rapidly: Rotary drill = 10-20 seconds Percussion drill = 40-60 revolutions

Elapsed time = 3-<4 minutes

Remove drill and drive adaptor, install jacking extension, jack and related hardware.

Elapsed time = 7-8 minutes
minimum to start

6. Load anchor bar to calibrated gauge value (33,000 lb minimum load on bolt), tighten nut on anchor bar until gauge pressure starts to drop (load transfer point). See page _____.

Elapsed time = 15-18 minutes maximum to complete

NOTE: Elapsed times based on cartridge temperature of 55 - 60 degrees Fahrenheit.

الدوار القرريجي والمتداني فتهير للبين أرافي يرسوها بخيد للجافر فالمدرة الكامات الماقيط فأفتح والأرجاب ومعجات

LOADING FASLOC-T CARTRIDGES

Prior to cartridge installation, holes will have been inspected for conformance to required diameter, drill depth and any obstructions.

LOADING SEQUENCE

- 1. Fasloc-T color code "green"
 1 2 minute gel time
 5 required
- 2. Fasloc-T color code "blue"
 15 30 minute gel time
 17 required

Cartridge length = 12" standard length. Top of last cartridge will be approximately 3 feet below grade.

 $\frac{\mbox{Verify}}{\mbox{loading}}$ lst cartridge reaches bottom of drill hole prior to loading balance of cartridges.

Verify temperature of Fasloc-T cartridges prior to installation. See time/temp chart in Dupont brochure.

COMMENT TO

ANCHOR BAR PRESTRESSING

Start of applied prestressing load is dependant on bottom 1-2 minute cartridges developing strength within allotted time. Temperatures colder than 55 degrees Fahrenheit will increase the minimum time interval prior to starting prestressing load.

with all slack removed in jack arrangement subsequent jacking should result in increasing gauge pressures with no indication of relaxation. The maximum elongation of the anchor bar at full applied load will be approximately 0.21 to 0.24 inches.

Excessive movement other than normal elongation at top of anchor bar could indicate insufficient bond time for 1-2 minute cartridges or general failure of anchor bar.

CALIBRATION

Calibration of Contractor furnished jack(s) will be done by Corps of Engineers.

Calibration equipment (Contractor furnished)

Enerpac - Mini hydraulic load cell Model No. LM-2506 50,000 lb capacity See catalog data

MINI-HYDRAULIC LOAD CELLS Compression type up to 300 tons

Used for accurate force measurement in:

- PRESSING WEIGHING
- TESTING • PRODUCTION PROCESSES • QUALITY CONTROL

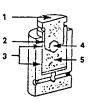

EXCLUSIVE FEATURES:

- 1. SWIVEL LOADING PAD Aligns load with load cell - reduces eccentric loading for longer life.
- 2. SELF-CENTERING O-RING Automatically self-levels the top pad when not loaded.
- 3. PLUNGER RETAINER RING & BUNA-N TYPE SEALS — for trouble-free performance under high compressive loads.
- 4. UNIQUE LOAD PIVOT BALL Low position of swivel-type ball transmits the load to a lower point in the plunger — reduces side loading and friction.
- 5. BRONZE PLATED PLUNGER Eliminates steel on steel contact for low friction.

These completely portable compression type load cells read the actual loads or forces being exerted on or within your equipment, your fixtures, or weight measurements. Just insert the load cell where force measurement is needed and read the gauge in lbs. or kg. of force. An economy tool-with accuracy to ±2% full scale reading.

Gauges are calibrated for force readings and read in pounds and kilograms. Direct mounted gauges have a 4" face. Remote mounted gauges have a 41/2" face.

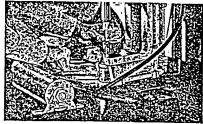

Gauges are equipped with a maximum indicating pointer to indicate the maximum pressure developed after a test is completed or to pre-select a desired pressure or load. Red pointer with plastic face plate cover follows regular gauge pointer as pressure increases, then remains at maximum reading when pressure cycle ends. Regular pointer returns to zero and maximum indicating point resets to zero for next test or run.

REMOTE MOUNTED GAUGE WITH 6' HOSE

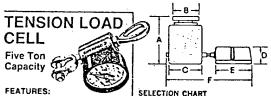

200,000 LBS. LH-10006

VERSATILE AND LOW COST TEST SYSTEM

VERSATILE AND LOW COST TEST SYSTEM

This manufacturer of disposable pens, lighters and shavers designed a test system which includes an LH-1002 Load Cell with its loading pad positioned within the opening of the bed of an A-310 Arbor Press Frame (page 68). An RR-1010 Double-Acting Cylinder (page 18) powered by a P-84 Hand Pump (pages 24-25) is mounted on the press frame to supply force to test samples while the load cell, with an accuracy of ±2% full scale, measures this force. This system costs under \$2,100 and allows the lab to study design concepts, simulate and delect production problems and determine the design, manufacture and use of production assembly equipment.

FEATURES:

- Economical Less costly than most other tension devices
- Nickel plated to reduce rust and corresion
- Factory sealed for accuracy
- Stored in cushioned metal case

Used for tension measuring applications such as lift trucks. cranes, drawbars, pull tests, etc. Self-contained hydraulically operated units measure tension in 200 pound increments. Equipped with maximum indicating pointer for reading pre-selected pressures or loads. Accurate to ±2% full scale. Includes hook and eye on either end for easy installation.

WILLIAMS RESIRVANGEOUNC WHITE REEDER

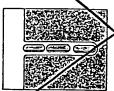

S6R RESIN CARTRIDGES

Williams resin cartridges consists of two components (1) quality polyester resin of out and (2) its catalyst. These precisely measured quantities are separated by a thin plantic film and are enclosed by this same film. After holes are drilled, the sausage shaped cartridges are inserted. When rotating a deformed rod through the cartridge and into the hole, the components are mixed and the curing action begins. When cured, the comprehensive strength of the resin is stronger than the surrounding rock.

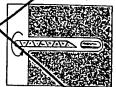

EASY INSTALLATION INSTRUCTIONS

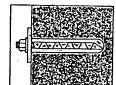

- Drill hole 1-2 inches shorter than bar length (do not overdrill).
- Use rolary-percussive equal ment, not diamond drifts.
- Clean hole of dust and debris

- Insert proper number of artridges.
- Resin should totally cover bolt. Refer to chart for proper amount.

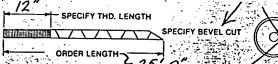

- Rotate bar slowly intil it reaches the end of the hole.
- Spin the bar for 20:30 seconds, as rapidly as possible.
- The bar should have a **
 minimum of 75 rotations.
- At 200-250 rpm a 15-20 second rotation is sufficient.
- Spin attachments are available from Williams for bolts and drills.

- Hold bar in place for 30-60 seconds, until the resin hardens:
- If the bar sags when the drill is removed, reatlach the drill and hold the bar in place that it sets.
- Resin should totally cover bolt. Refer to chart for proper amount.

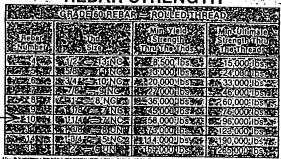

Williams threaded rebar, resin and grout collars are recommended for rock bolting situations where anchor head assemblies are not applicable. When anchoring into overhead situations the grout collar is ideal for keeping the correct amount of resin in the hole.

When ordering a bar to be used with resin cartridges, it should be ordered with a bevel cut to ald in shearing cartridges and mixing resin. Williams supplies avariety of threaded and deformed bars. For more information contact a representative.

When fully cured, the resin is stronger than rock most other materials into which it is likely to be used. Please refer to the following test data which is based on our standard resin cartridge. WILLIAMS FORM can supply higher or lower resin strengths to suit the application. Please contacta WILLIAMS representative for further information. K3F-21 DRILL HOLE GAUGE

This new hole gauge from Williams measures the hole diameter with foll bearing accuracy. This means the full bearing area of the rock bolt shell is measured - not just a contact point. The rugged design of unit permits it to slide to and out easily. Its simple operation requires no special training. Just a pull on the measurement rod will allow the gauge to be removed. Graduated measurements of hole diameters are accurately lineally stamped on

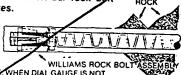

measurement rod to within 1/2" of hole diameter. The adjustable recalibration ring and lock nut simplify "in the field" recalibration of the unit. A checking ring pauge is also supplied. All parts of unit are stainless steel or galvanized to assure them of being corrosion resistant. The unit is available in any length with separate models for to 2" holes and 2" to 31/2" holes.

resin anchored bolf system
for civil engineering applications

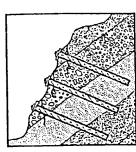

a need to improve rock support

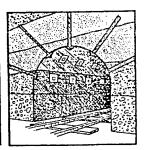

a. THE FASLOCE COMPONENTS

b. RIB STABILIZATION C. SLOPE

c. SLOPE STABILITATION

d. TUNNEL SUPPORT

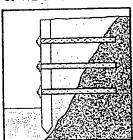

The purpose of a rock bolt system is to resist strata movement. Generally the load taken by the rock bolt support system depends largely on the development of frictional force between the surface of the rock and the rock bolt anchorage system. Anchorage integrity depends upon the extent to which these forces are developed and a rock bolt system should achieve as

much anchorage as possible with the inside surface of the hole in which it is placed. The FASLOC® resin anchored bolt system uses a high strength polyester resin to anchor the entire length of the steel bolt to the surrounding rock strata. (See illustration a.) This unification of the resin, bolt and strata layers provides the necessary strength and rigidity to

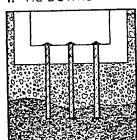

anchor the individual stratified layers and resist further movement and deterioration. Examples of typical installations are shown in the illustrations (b, c, d, e, f, and g). Theoretical analysis suggests that the reinforcement effect of the FASLOC resin bolt system may be increased by pretensioning the bolts to some value usually between

50% and 80% of the yield point of the bolts. This can be accomplished by using a fast-setting FASLOC resin at the "in-hole" end and a slower FASLOC resin "outby" that will set and hold the pre-tension that has been applied to the bolt. Pre-tension specifications are usually set by the designer. See page 9 for pre-tension installation techniques.

resin anchored bolf system

... composed of a unique resin cartridge and a steel bolt

h. THE CARTRIDGE

j. CROSS SECTION

I. THE BOLTS

The polyester resin in the cartridge is used to anchor the entire length of the bolt to the surrounding strata. This unification of the resin, bolt, and strata layers provides the necessary strength and rigidity to prevent the sag by acting as a reinforcement which anchors the individual stratified layers of rock into a single high strength beam. The two-compartment

cartridge shown in the illustration (h) above consists of a heat-sealed tube of MYLAR® polyester film clipped at both ends. One compartment contains a dark gray resin; the other, a white catalyst. A cross section of this structure is shown in the illustration (j) above. Two typical steel bolts are shown above (illustration i).

A film barrier of MYLAR

The light-weight, dimensionally

moisture from the outside.

resistance of MYLAR

quickly and thoroughly during the installation procedure. The Du Pont resin formulation is thixotropic and fast setting. This reduces viscosity during insertion of the bolt and permits relatively low force and torque. The results are fast installation, rapid achievement of full strength, and a minimum tendency for ungelled resin to drip from the holes during installation.

Table 1

Physical Properties of Cured Resin

Compressive Strength (PSI)	15,600
Compressive Mod. (10° PSI)	1.3
Shear Strength (PSI)	5,000
Flexural Strength (PSI)	4,000
Flexural Modulus (10° PSI)	1.7

Due to difficulty of preparing ASTM test specimens with fast gelling (setting) resins, above properites derived from 5-10 minute (0510) gel time FASLOC T. Field experience

indicates that all FASLOC T cured resins produce comparable anchorage strengths. Specific applications should specify field pull tests under actual job conditions. (See Table 2, page 4.)

Figure 1
Resin Strength vs. Cure Time

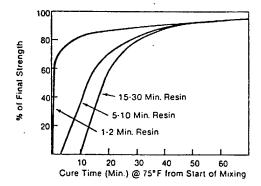

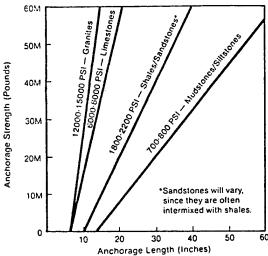

Figure 2 Resin Anchorage Related to Compressive Strength of Rock (Inches of Length/Pounds of Strength)

- This chart represents the range of anchorage strengths for estimating requirements.
- Depending upon the compressive strength of the rock being con-sidered, the diameter of the hole

may affect the anchorage strength — the larger the diameter, the larger the contact area.

3. Pull tests under field conditions should be used to determine actual requirements.

strata dowelled ... develops strong anchorage in a variety of strata

Competent anchorage has been obtained with the Du Pont FASLOC T system in a variety of formations. (See Figure 2.)

Field tests have shown that FASLOC offers increased resistance to anchorage failure caused by blasting or vibration.

tension internally with application of load

The combined anchorage strength of the resin and the bolt exceeds the yield point of the steel bolt. Pull tests dramatically illustrate the anchoring strength of the FASLOC T system. (See Table 2.)

1%" dia. holes - Grade 60 rebar#11 (1%" dia.) bolts.

NOTES: CLASS

- Massive to slightly blocky, no alteration, joint spacing 1.0 feet or greater.
- Moderately blocky, little or no alteration, joint spacing 0.5 feet or greater. Very blocky, moderately to highly altered, joint spacing less than 1.0 feet.
- Highly crushed and attered, non-plastic, abundant clay, joint spacing less than 0.5 feet.

smooth stress strain curve . . . no bleed off

Full-length resin anchored bolts provide effective resistance to changing rock strata stresses throughout their entire length, thereby assuring satisfactory stabilization of rock strata over long periods of time.

Strain-gauged, full-length grouted resin bolts installed in rock strata have shown that axial loads vary continuously along each bolt length. This is shown in Figure 3.

It is quite common to find portions of a bolt in compression while other parts are in tension.

Cyclic upward/downward movement has been recorded although the dominant trend is downward. (See Figure 4.)

resists vertical and lateral strata movement

The Du Pont FASLOC T system is designed to resist both vertical and lateral movements of rock strata, the most common cause of failure.

The full-length resin anchorage effectively seals wet, dripping holes and, in most cases, eliminates further deterioration of the hole and surrounding

complete

sealing of bolt

The Du Pont resin anchored bolt system is unaffected by sea water, fresh water, mild acids or mild alkalis.

strata. The fully-encased bolt

is also protected from eventual weakening due to

corrosion.

Figure 3
Axial Load Variation
Over Bolt Length 0-50 Days

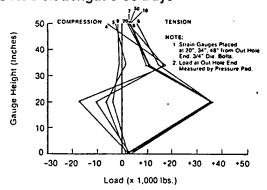

Figure 4
Typical Strain-Gauged Bolt Load-Strata
Separation Time Series.

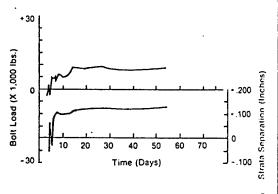

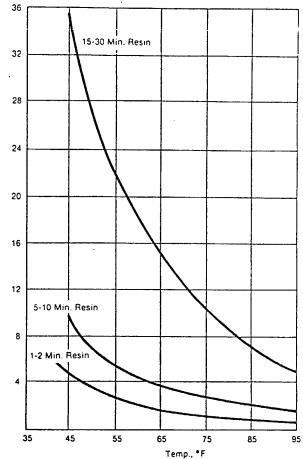

Figure 5 Gel Time

A wide range of gel times is offered for varied conditions. The standard one-minute (0001) and two-minute (0002) gel times meet most underground mine requirements.

However, for special conditions, where installations are difficult or full length anchored tensioned bolts are used, two additional longer gel times are available. These are 5-10 minute (0510) and 15-30 minute (1530). The gel times are standardized at 55-60°F.

The effect of temperature on gel times is shown in Figure 5.

Non-Tensioned Bolts

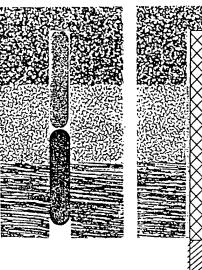

- Insert necessary resin cartridges into the hole.
- Push the bolt into the hole to a point just below the roof line. Turning of the bolt during this step is optional. Threaded bolts may be pushed home.
- Rotary drills:
 Rotate the bolt rapidly for 10-20 seconds.
 Percussion drills:
 Rotate the bolt 40-60 revolutions.
- Push the bolt upward with the maximum thrust available from the machine and hold until resin hardens. Do not rotate after Step 3. Damage to partially gelled resin may result

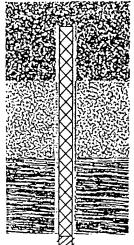

The recommended installation procedures should be followed very carefully to insure successful application of FASLOC resin bolting.

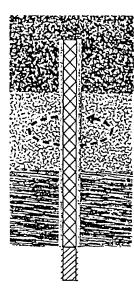

☐ Resin bolts should be installed as soon as possible in newly-exposed rool. Roof that has been allowed to shift or sag offers the least chance for successful support.

☐ Do not use ruptured or broken cartridges. Damaged cartridges should be removed from the mine or job site.

Pre-Tensioned Bolts

After drilling hole, insert necessary resin cartridges with the fast-setting cartridges (shown in blue above) at the "in-hole" end to anchor the bolt prior to tensioning. Then insert the slow-setting cartridges outby (shown in black above).

> Caution: If hole has been overdrilled, be certain that sufficient fast-set cartridges are used at the back of hole to develop the bolt anchorage required for the subsequent pre-tensioning.

- Push the bolt into the hole. Turning of the bolt during this step is optional.
- Rotary drills: Rotate the bolt rapidly for 10-20 seconds. Percussion drills: Rotate the bolt 40-60 revolutions.
- It may be necessary to use quick-setting mortar to provide the proper surface for mounting the bearing plate on the rock surface at right angles to the bolt. As soon as fastsetting cartridges gel but before slow-setting cartridges gel - begin the pre-tensioning. Pretensioning may be done with hydraulic ram, mechanical tensioner, or torque wrench depending on requirements set by designer. When slowsetting cartridges gel, the installation is complete.

For maximum shelf-life, FASLOC cartridges should be stored away from direct sunlight in a reasonably cool, well-ventilated, dry arca. Storage life is up to 1 year dependent on ambient temperature conditions. Under adverse conditions shelf-life is reduced. To insure proper storage, the product should not be subjected to temperatures in excess of 85°F for prolonged periods. Storage is recommended under cover, on original pallets with adequate ventilation. If stored in trailers in hot weather, doors should be left ajar or a sun screen erected over the trailer. Conversely, while cold storage does not adversely effect the shelf-life of FASLOC, it should be warmed to a range of 50°-60°F before using to assure gel times within the specified range (see Figure 5). The time required for boxes of FASLOC to warm or cool to ambient temperature is dependent on both the initial temperature and how the boxes are stacked. Where the initial temperature is anywhere between 25° and 85°F, cases will come within 5° of ambient temperature in 48 hours when

stäcked in single columns with 4 sides of each box exposed to the air. Multiple columns should be separated by at least 2 inches to assist air circulation between columns. Resin cartridge cases should be stacked preferably six high with a maximum never to exceed nine cases. Overstacking will crush the cases resulting in ruptured resin cartridges. Pallets should not be stacked. It is essential that stacks be rotated so that the oldest stock is the first out.

The superior quality of the Du Pont FASLOC® T resin bolt system is assured through a three part quality control program.

- ingredient testingin-process control tests
- finished product acceptance testing

Testing levels and specifications for each of these programs have been established statistically based on actual historical data, to insure the customer

receives a uniform quality product which will perform dependably under field conditions.

Ingredient Testing
All vendors are required to
certify that each lot of
ingredients meets our stringent specification and
furnish data that supports
the certification. In addition
each ingredient is rechecked
and verified through testing
in our laboratory.

In-Process Control Test Testing of materials as mixed, prior to packaging is conducted at specified frequencies and again must meet specifications for the following parameters:

- resin viscosity
- gel time at 55°F and 75°F
- percent of activator
- percent of inert filler

In addition mixed samples of resin and activator are tested for.

- · shear strength
- · pull strength

Finish Product
Acceptance Testing
To further assure quality
of product being shipped the
following seven parameters
of the finished product,
although automatically
controlled, are manually
inspected and tested on a lot
to lot basis.

- cartridge length
- cartridge diameter
- resin to activator ratio
- viscosity of resingel time
- cartridges/box
- . box labeling and coding

In addition samples of each lot are retained at the plant for future reference, if required.

The data generated by all the testing is reviewed on a regular basis by our Quality Control Engineer who guides our revisions to testing levels and specifications in a continuing effort to provide improved quality products for the customer.

10

safe handling precautions

how to put DuPont FASLOC°T to work for you

Caution: Do not open or puncture cartridge. Physical contact with liquid contained in cartridge may cause mild irritation. Safety glasses or eye shield should always be used when roof bolting is done. In case of eye contact, immediately flush with plenty of water for at least 15 minutes. Call a physician.

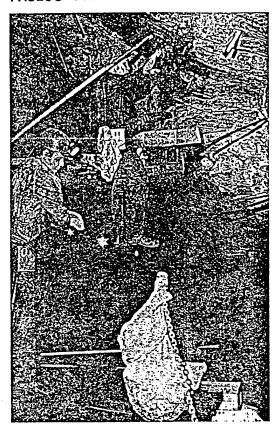

In case of skin contact, flush skin with water. Prolonged contact with skin may cause mild irritation. Irritation should subside when material is removed.

Cartridges are filled with inert fillers, water, polyester resin and activator (active ingredients include low levels of styrene and modified benzoyl peroxide). Du Pont resin cartridges are for industrial use only and are intended for use in conjunction with bolts. The relationship between hole dimensions, bolt size and the size and number of cartridges is critical to good performance. Your Du Pont representative will be glad to assist in determining the proper combinations for specific applications.

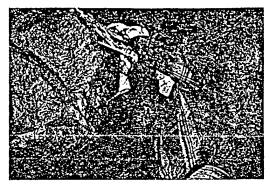

For technical information call 1-800-332-3308. To place an order or other sales service assistance call 1-800-255-8384.

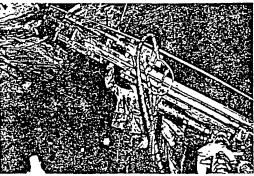

The facts stated and the recommendations made herein are based on our research and research of others, are offered free of charge, and are believed to be accurate. No guarantee of their accuracy is made, however, and the products discussed are distributed without warranty, expressed or implied, and upon condition that recipients shall make their own tests to determine the suitability of such products for their particular purposes. Likewise, statements concerning the possible uses of our product are not intended as a recommendation to use it in the infringement of any patent, whether owned by Ou Pont or by others.

TECHNICAL DATA

Sure-Grip High Performance Grout™

Non-Shrink, Non-Metallic, High Early Strength

PRODUCT DESCRIPTION:

Sure-Grlp High Performance Grout Is a ready-to-use, nonshrink, non-corrosive, non-metallic grout formulated and produced with the highest quality raw materials available. It is a cement-based grout designed to deliver a high rate of flow with excellent density (for dynamic loads) and a high compressive strength. In fact, Sure-Grip Grout not only delivers high compressive strength quickly - 5,000 psi in one day - but it also delivers an outstanding compressive strength at 28 days, over 10,000 psi! Sure Grip Grout's high early strength means an earlier project completion time for contractors and less down time for machines. Sure-Grip is also designed to provide an effective load bearing surface through its non-shrink properties and it contains no chiorides or any component that could cause corrosion, rusting or bleeding.

PURPOSE:

Sure-Grip High Performance Grout is an ideal product for MEETS SPECIFICATIONS: Interior or exterior grouting of architectural and structural precast concrete components, structural column base plates, machinery bases, anchoring bolts, cable anchorages, dowels, bearing pads, keyway joints and crane rails. It also finds excellent applications in power plants, steel mills, paper mills, oil refineries, food plants as well as sewage and water treatment plants.

ADVANTAGES:

- High Compressive Strength Quickly . 5,000 psi in One Day
- Less Downtime For Machines
- Contractors Can Finish Projects Sooner
- High Ultimate Compressive Strength -10,000 psl in 28 days
- Non-Shrink
- Non-Metallic/Non-Corrosive
- High Density
- Low Water Requirements
- High Fluidity/Pourable/Pumpable
- Resistant to Heat and Thermal Shock
- Interior/Exterior Applications
- Resists Water and Salt Penetration and Damage From Freeze-Thaw Cycles
- Approved by Numerous State D.O.T.'s

Corps of Engineers Specification for Non-Shrink Grout: CRD-C 621

ASTM C-827 - Sure Grip Grout yielded a controlled positive expansion

Sure-Grip High Performance Grout has been approved by numerous State D.O.T.'s and other approval agencies.

(Continued on Back)

TEST RESULTS - CORPS OF ENGINEERS CRD-C 621

Fluidity	Water	Flow®	E	xpanslon (%)		Compressive Strength (PSI)				
	Content		@3 days	@14 days	@28 days	@1 day	@3 days	@7 days	@28 days	
Plastic	6 pts.	100	+.02	+.01	+.01	6500	8000	10,000	12,500

Fluid	8-9 pts.	30 sec.	+.01	+.01	. +.01	4000	7000	8500	10,000	

⁽a) Minimum and moderate fluidities are measured at five drops on a flow table corresponding to CRO-C 226. The special minimum fluidity is 100-125, and for moderate fluidity 124-145. High fluidity is measured through a flow cone per CRD-C 811 with a specified efflux time of 10-30 seconds.

WARRANTY

The Dayton Superior Corporation (The Company) will refund the price of or replace, at its election, any product which is finds to be defective provided the product has been used properly. EXCEPT AS EXPRESSLY STATED ADOVE, THE COMPANY MAKES NO WARRANTY OF MERCHANTALILITY AND NO THE COMPANY MAKES NO WARRANTY OF MERCHANIABILITY AND NO WARRANTY OF FITNESS FOR ANY PARTICULAR PURPOSE NOR DOES IT MAKE ANY WARRANTY, EXPRESS OR IMPLIED, OF ANY NATURE WHAT-BOEVER WITH RESPECT TO THE PRODUCT OR THE USE THEREOF. BY WAY OF ILLUSTRATION AND NO LIMITATION, IN NO EVENT SHALL THE COMPANY BE LIABLE FOR DELAY CAUSED BY DEFECTS, FOR ILLUSTRATION AND NO CONSCIUENTIAL NAMAGES OR

DISTRIBUTED BY:

Dayton Superior Corporation

APPLICATION INSTRUCTIONS: SURFACE PREPARATION:

Thoroughly clean all contact surfaces. Existing concrete should be strong and sound. Maintain contact areas between 50 degrees and 80 degrees F, before grouting and during curing period. For hot and cold weather applications, contact Dayton Superior. Thoroughly wet concrete contact area 24 hours prior to grouting, keep wet, and remove all surface water just prior to placement.

MIXING:

A mechanical mixer with rotating blades is best. Small quantities can be mixed with tools by hand. Place approximately ¼ of the anticipated mix water into the mixer, add the grout and mix, adding the minimum additional water necessary to achieve the desired consistency.

WATER REQUIREMENTS

Dosired MixWater Per 55 lb. BagPlastio6 PintsFlowable7 PintsFluid8-9 Pints

Mix for a total of five minutes ensuring uniform consistency. For placements greater in depth than 3", up to 25 pounds of washed pea gravel (%" maximum size) may be added to each 55 pound bag of grout.

The approximate working time (pot life) is 30 minutes. This will vary somewhat with ambient conditions.

PLACEMENT:

Grout should not be placed so as to avoid entrapped air pockets. Grout should not be over-worked causing segregation. Vent holes should be provided where necessary. Forms must be sealed to prevent water or grout loss. When possible, grout boit holes first. Placement and consolidation should be continuous for any one section of the grout, such equipment should be shut down for a period of eight hours.

FINISHING AND CURING:

Forms may be removed when grout is completely self-supporting. Cut away areas where grout excessively restricts movement of stoot, i.e., edges of base plates, etc. For best results, grout should extend downward at a 45 degree angle from the lower edge of the steel base plates or similar structures. Exposed grout surfaces should be cured. Dayton Superior recommends using: Day-Chem Cure & Seal: 25%. Maintain the temperature of the grout and contact area at 50 degrees to 80 degrees Fahrenhelt for a minimum of 24 hours.

SPECIAL CONDITIONS:

In hot or cold temperatures, or unusual conditions such as mass pours, thin layers, extreme temperature service, restraint of movement, or long distance pumping are anticipated, contact DSC for specific recommendations.

APPROXIMATE YIELD:

.46 cubic feet per 55 lb. bag

.62 cubic feet per 55 lb. bag extended with 25 lbs. of washed pea gravel (%" maximum size)

PACKAGING:

55 lb. multi-wall, plastic fined bags (24.95 kg.)

CLEAN-UP:

Use clean water.

LIMITATIONS:

Do not retemper after initial mixing. Do not add other cements or additivies to Sure-Grip Grout.

Setting time for Sure-Grip Grout will slow down during cold weather (less than 50 degrees F.) and spood up during hot weather (greater than 80 degrees F.). Contact Dayton Superior for specific recommendations.

Exposed grout surfaces should be cured. Dayton Superior recommends using: Day-Chem Cure & Seal: 26% (meets ASTM C-309).

Store in a cool, dry area that is free from moisture and direct sunlight.

WARNING:

Avoid direct contact with skin and eyes. Product contains Portland Cement. Wash exposed skin area promptly with water. May cause skin Irritation and possibly cement burns. In case of eye contact, flood eyes repeatedly with water and call physician. Do not take internally. Harmful if ingested. Keep product out of reach of children. See Material Safety Data Sheet for additional information.

AEROSPRAY 70 binder

PRODUCT BULLETIN EN 100B

AEROSPRAY® 70 binder is the latest development in polymeric soil stabilizers and dust control agents. It functions to reduce and eliminate surface erosion caused by wind and rain. At low treatment levels, AEROSPRAY 70 binder works as an effective binding agent which also forms a surface film coating when used in higher concentrations.

Advantages

. EXCELLENT RESULTS -

Stabilizes surface soil and prevents erosion by wind and rain while leaving the esthetic appearance of the treated area unaffected.

. ECONOMICAL -

AEROSPRAY 70 binder controls dust in areas of light traffic without the need for costly surface treatments.

. STABLE -

Extremely resistant to sunlight and completely safe for both germinating and growing plants.

EASY TO USE & SAFE TO HANDLE —
 AEROSPRAY 70 presents no fire or
 explosion hazards either in storage or
 during application.

Principal Uses

AEROSPRAY 70 binder has been proved effective in a wide range of stabilization problems on several types of soils and mine tailings under varying environmental conditions. Some areas where AEROSPRAY 70 binder might be used effectively include:

Agriculture

- As a binder to prevent erosion during seed germination in establishment of vegetative cover.
- To prevent damage to seedlings by dust blown from adjacent locations.

Aviation

- The suppression of dust on the perimeter areas of runways and taxiways.
- Used in conjunction with the construction of runways, taxiways, and hanger ramps at secondary airports.

ENGINEERING CHEMICALS, AMERICAN CYANAMID COMPANY, WAYNE, NEW JERSEY 07470

ं राज्यात वार्य का राज्य स्थाना स्थाना स्थाना स्थाना स्थाना स्थाना स्थाना स्थाना स्थाना स्थाना स्थाना स्थाना स

L

Conservation

- · Sand dune stabilization.
- · Dust suppression.
- · Erosion control.

Construction

- · Dust suppression on job sites.
- To complement road construction.
- As a binder for both seeds and hay mulch on newly graded slopes and roadway embankments.

The Home

- As an aid in establishing lawns by preventing seed bed erosion during germination, expecially in high slope areas.
- · The construction of walkways.

Mining

- The stabilization of tailings piles to control environmental pollution.
- To minimize the losses incurred in transporting crushed coal, or ore in open vehicles; such as, railroad cars, trucks, and ships, etc., by binding the exposed surface.

Water Management

- · Water catchments.
- · Pond liners.
- · Irrigation ditch liners.

Typical Properties

AEROSPRAY 70 binder is supplied in concentrated form, and requires only dilution with water in the field to the desired level for application. Typical properties of AERO-SPRAY 70 binder as supplied are:

AEROSPRAY 70

The binding and film forming properties of AEROSPRAY 70 binder result from the coalescing of the polymer particles as the water is lost by evaporation into the air, or by absorption into the surrounding substrate matrix. Drying time is dependent upon several factors, including the dilution ratio, application rate, and environmental conditions such as wind velocity, temperature and relative humidity. It can range from twenty minutes to several hours. To achieve optimum results, AEROSPRAY 70 should not be applied when the soil temperature is lower than about 45°F.

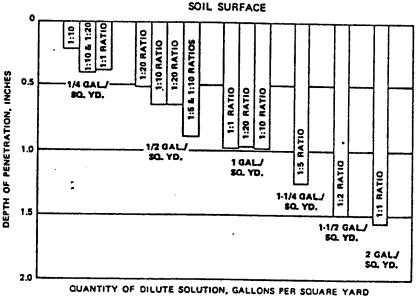

AEROSPRAY 70 will provide a coating that can be made to vary from a tough continuous surface film of polymer to an almost imperceptible web of microscopic threads which fill the interstitial voids in the soil matrix, literally tying the particles together. The characteristics of the coating are dependent upon several things; primarily

the dilution ratio and application rate of AEROSPRAY 70 binder and the degree of compaction and particle size distribution of the substrate.

Binding

When AEROSPRAY 70 binder is mixed with 1 part or more of water and applied to non-compacted substrates similar to sand, no surface film will be formed. Instead, the mixture will penetrate into the matrix and bind the individual particles. Experience has shown that the depth of penetration is more dependent upon the quantity of solution. applied rather than its concentration. Figure 1 illustrates this for solutions of AEROSPRAY 70 binder and water ranging from 1 part AEROSPRAY 70 binder in 1 part water to 1 part AEROSPRAY 70 binder in 20 parts water. The mixtures in the example were applied to a sandy silt extracted from lower New York Bay.

FIGURE 1
PENETRATION OF AEROSPRAY 70 BINDER IN PORT ELIZABETH, N.J., SOIL

minimized the second of the second se

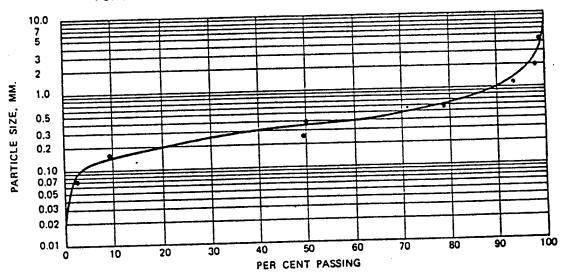

Figure 2 shows the distribution of particle sizes in the test soil. Information about the structure of the substrate to which the AEROSPRAY 70 will be applied is helpful in determining optimum application rates, because results are heavily dependent on the substrate characteristics. An increase in the proportion of larger particles, as for example, in coarse sand, would result in greater penetration for a given quantity of AEROSPRAY 70 binder. Where there are greater percentages of fine particles, as in soils rich in clay, penetration is reduced. Under these conditions, AEROSPRAY 70 binder will form a surface film with very little penetration when applied in a solution of 1, 2, or more parts AEROSPRAY 70 binder to 1 part water, as described above.

The strength of the layer of bound soil will increase with increasing AEROSPRAY 70 binder concentration for a fixed application rate. The permeability of the treated soil will decrease. This is because of the manner in which AEROSPRAY 70 binder performs its

function in dilute mixtures. The individual soil particles are laced together by a web of polymeric bridges. As the quantity of AEROSPRAY 70 binder is increased, the network of bridges becomes more intricate, until all the voids in the soil matrix are filled with the polymer. The desirability or undesirability of completely filling all of the void space in a given substrate layer will, of course, depend upon the cost-performance objectives of the particular application. In the stabilization of walkways, parking lots, and other light-trafficked surfaces, a strong impermeable surface is desired, and a relatively heavy application of AEROSPRAY 70 binder, perhaps in a mixture of 1 part AEROSPRAY 70 binder to 1 part water, and applied at the rate of 0.5 or more gallons per square yard would be required. The optimum rate of application and dilution ratio should be determined by preliminary examination on a sample of the material to be treated, followed by a small field test.

J

FIGURE 2
PORT ELIZABETH SAND: PARTICLE SIZE VS. PER CENT PASSING

AEROSPRAY 70

If AEROSPRAY 70 binder is applied lightly, in dilutions of 1 part to 20 or more parts of water, at ½ gallons per square yard; a high degree of binding can be expected, but the surface will remain permeable to water to the extent that seeds will germinate through the bound layer. This feature is invaluable in situations where the desired objective is long-term erosion control. The seeds will be held in place by the polymeric web until they have a chance to germinate. Upon germination, the plant cover will break up the bound layer, and establish itself as the first line of defense against erosion.

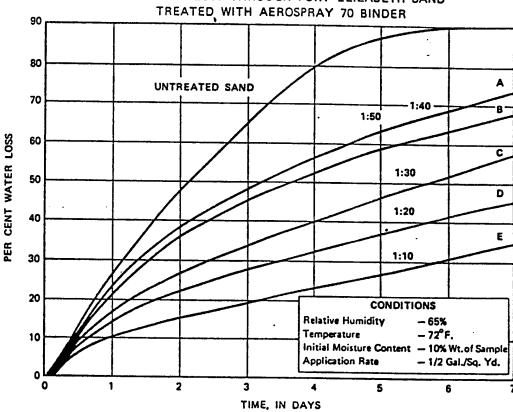

Treatment with AEROSPRAY 70 will substantially reduce evaporation losses. This is

particularly important in areas where farming is conducted under conditions where water is scarce or where water must be brought in by irrigation.

Figure 3 illustrates moisture loss for samples of sand treated with various concentrations of AEROSPRAY 70 binder ranging from one part AEROSPRAY 70 binder in ten parts water to one part AEROSPRAY 70 binder in fifty parts of water. At the beginning of the experiment half of the samples contain 10 per cent by weight of water. Note that the untreated sand lost nearly three times as much water in one week as did sample E. Note that even a treatment with a very dilute solution of AEROSPRAY 70 binder (sample A) was of significant benefit.

FIGURE 3

MOISTURE LOSS THROUGH PORT ELIZABETH SAND
TREATED, WITH AEROSPRAY 70 BINDER

Continuous Films

Very concentrated mixtures, containing more than 2 parts of AEROSPRAY 70 binder per part of water, form a continuous film when applied to substrates that are highly compacted, contain a high percentage of fine particles, or both. An example of this type of substrate is compacted clay. Application of concentrated AEROSPRAY 70 binder mixtures on clay will produce a tough, continuous film, impermeable to water when applied at a rate of 1 to 3 gallons per square yard. This is suitable for surfaces subjected to intermittent light vehicular traffic, such as highway shoulders, airport ramps and taxiways, and temporary road surfaces.

Application Techniques

AEROSPRAY 70 binder requires only dilution with water to prepare it for use. Although exceptionally stable to dilution with hard water, it is good practice to use the cleanest water available for dilution and equipment clean-up.

Dilution of two parts AEROSPRAY 70 binder with 1 part of water, by volume, results in a fluid consistency suitable for spray or spreader application. However, the excelent dilution stability of the material permits further reduction to meet specific application demands. Experience has shown that simple mixing ratios in the following range will cover most requirements:

Part of Vo AEROSPRAN 70 binder	Wester .	Approximate Solids, Per Cent by Weight
2	: 1	41.1
1 1	1	31.5
1	10	5.8
1 :	•	2.9
1	•	
1	: 50	1.2

AEROSPRAY 70 can be used to line farm ponds and irrigation canals to reduce the loss of water by penetration into the surrounding

soil. If the film liner is damaged by livestock, etc., it can easily be repaired by simply pouring some fresh AEROSPRAY 70 binder over the tear. The new material will bond securely to the old to form a seal. For applications with less severe service requirements than those described above, the quantity of AEROSPRAY 70 binder can be sharply reduced. The optimum dilution ratio and application rate are dictated by the characteristics of the substrate and the desired results of the treatment.

As a general rule, the best practice is to add the water to the material rather than the reverse. Use a recirculating pump for mixing if the application tank is not equipped with a stirrer. Manual mixing of drum quantities will suffice to produce a homogeneous dispersion.

When 10 per cent water is added to AEROSPRAY 70 binder, the viscosity of the mixture is reduced considerably. When 20 per cent or more water is added to AEROSPRAY 70 binder, the viscosity approaches that of water. This coupled with the excellent mechanical stability of AEROSPRAY 70 allows a wide latitude in the selection of methods of application of AEROSPRAY 70. In general, any method that will cause the mixture to strike the surface in a low speed spray with uniform coverage is acceptable.

Application Equipment

The specific design of application equipment will be determined by the typography of the job site. In general, much of the equipment that is available for application of liquid fertilizers and insecticides, and for spreading asphalt emulsions can be used to apply AEROSPRAY 70 with little or no modification. Such equipment can be purchased with oversize tires to permit its use on unstable surfaces, like sand dunes. Hand-held

AEROSPRAY 70

29/

pressure sprayers, commonly used for applying insecticides can be used for small jobs or for patching. A gravity feed water sprinkler truck can be used for applying the material to roadways, shoulders, parking lots, and other similar surfaces. The environment of each specific job will guide the selection of the proper application equipment.

In any case, the application system should consist of a tank for mixing and storing AEROSPRAY 70 binder and water, and one or more spray nozzles. The energy necessary for spraying the material can be supplied by pumping, or by pressurizing the hold tank. Suitable pumps include the Series 151 "Viking" pump, the "Blackmer" type GL sliding vane pump, and the "Waukesha Dualobe" pump. Centrifugal pumps can be used for handling diluted AEROSPRAY 70 binder and water mixtures. The concentrate is much to viscous for efficient use of centrifugals. A "Moyno" pump, fitted with a stainless shaft and rotor, also provides excellent service.

In all cases, pump shafts and bearings should be provided with a water-proof lubricant sealed off from the circulating AEROSPRAY 70. Since it is a water based material, AEROSPRAY 70 is not self lubricating. If it is allowed to leak into the pump bearings, rubbing friction may cause it to coalesce on bearing surfaces and may cause the pump to bind.

coarse droplet spray at the desired delivery rate. High shear forces in the nozzle, caused by improper nozzle configuration, or excessive spraying pressure are to be avoided, as they will cause the product to atomize and, in effect, spray dry on its way to the target substrate. A Model 1/4 T9520 nozzle, supplied by Spraying Systems, Inc. has been used effectively to produce a flat fan spray pattern with low atomization at approximately 20 gallons per minute with 40 psi. nozzle pressure. Application rates can be increased by selecting a larger nozzle of a similar configuration or by teaming several nozzles on a spray bar. It is best to position the nozzle between 6 and 12 inches above the target to minimize material losses.

Equipment clean-up is simple and easy, but must be done before the coating dries out. Equipment should also be clean BEFORE use. Tanks and lines need only be washed with water containing a small quantity of detergent. In general, it is desirable to start with a minimum of added water under recirculation, and then gradually increase the dilution while draining the equipment. Flush with fresh water until it runs clear.

As with all aqueous systems, AERO-SPRAY 70 will promote rusting of plain steel. Corrosion resistant materials are desirable for permanent installations. Galvanized iron, brass, or other zinc containing mixtures should not be used.

Spray nozzles should be selected to give a

SHIPPING

AEROSPRAY 70 binder is available in bulk shipment, as well as in 50-55 gallon fiber or steel, non-returnable drums (500 lbs. net wt.)

TECHNICAL SERVICE

Technical Service and information for making the best use of this product are available through your Cyanamid Sales Representative or nearest Sales Office.

Specification

AEROSPRAY® 70 binder, a polyvinyl acetate emulsion resin, containing 60 ± 1% total solids by weight, shall be applied in accordance with manufacturer's recommendations.

MSDS NO. 0288-01 AEROSPRAY® 70 Binder

EXPOSURE Engineering controls are not usually necessary, if good hygiene practices are strictly followed. Respiratory protection is generally not required during normal operations.

MSDS NO. 0288-01 AEROSPRAY® 70 Binder

SPILL OR LEAK PROCEDURES

STEPS TO BE TAKEN IN CASE MATERIAL IS RELEASED OR SPILLED:

Cover spills with some inert absorbent material; sweep up and place in a waste disposal container. Flush area with water.

WASTE DISPOSAL

Disposal must be made in accordance with applicable governmental regulations.

SPECIAL PRECAUTIONS

HANDLING AND STORAGE/OTHER:

None

Page 2 of 2 • DACW69-88-C-0001 Modification P00007

The total contract price is reduced by \$2,835.00. The total contract completion date remains unchanged.

This adjustment constitutes compensation in full on behalf of the contractor and its subcontractors and suppliers for all cost and markups directly or indirectly attributable to the change ordered herein, for all delays related thereto and for performance of the changes within the time frame stated.

areas where the slurry trench is under any permanent roads, temporary access roads and where any haul roads intersect the slurry trench.

If in those areas where the cap is eliminated, additional maintenance is required, it will be performed at no additional costs to the government.

This modification was formerly referred to as Change "BL", "Value Engineering Proposal No. 7".

Payment for all costs and credits for the changed work will be made at the agreed prices hereby established and listed below:

Item No. P00032-1	Description VE No. 7 -	Qty	Unit	Unit Price	Amount Increase Decrease
P00032-2	Revise Slurry Wall Cap VECP Incentive Adjustment Paid	1	JOB	SUM	\$57,777.78
	to the Contractor	1	JOB	SUM	\$31,777.78

Net Decrease to Contract Amount - \$26,000.00

The contract amount is decreased by \$26,000.00. The contract performance time remains unchanged.

It is also understood and agreed that this adjustment constitutes compensation in full on behalf of the Contractor and its subcontractors and suppliers, for all costs and mark-ups directly and indirectly attributable to the change ordered herein.

If the foregoing modification is acceptable, it is requested that you complete Blocks 15A and 15C, sign in Block 15B of the form, and return the original to this office (ATTN: CEORH-CT).

Page 2 of 2 Contract No. DACW69-88-C-0001 Modification P00096

One new lump sum item for "Settlement of Claim for Dewatering Wells" shall be added to the contract as shown below. This item shall provide compensation for all costs arising from said claim and shall include all markups for both prime contractor and subcontractor, as well as any payment for interest which may be due.

Item No.	Description	Quantity/Unit	Unit Price
P00098-1	Settlement of Claim for Dewatering Wells	l Job Sum	\$26,500.00

The contract price is increased by \$26,500.00. The contract time is unchanged.

This adjustment constitutes compensation in full on behalf of the contractor and its subcontractor for all costs and markups directly or indirectly related thereto, including impact, if any, on unchanged work and, for all interest which may be due. It is understood and agreed that upon acceptance of this modification and payment of said increase in contract price, the contractor hereby releases and forever discharges the Government from all causes of action, claims and demands which have been or could be made upon the basis of the facts giving rise to the aforementioned claim and appeal. Also, the contractor agrees to release, waive and forever abandon all claims to attorney's fees and other expenses arising from the appeal docketed as ENG BCA No. 5596 under the Equal Access to Justice Act (Pub L. No. 99-80, 99 stat. 183 [codified at 5 U.S.C. 504 and 28 U.S.C. 2412]).

If the foregoing modification is acceptable, it is requested that you sign in block 15B, complete blocks 15A and 15E and return the original to this office (ATTN: CEORH-CT).

s modification is also designated as Change "TF".

Since the Contractor refuses to recognize a credit for the early removal of the Buffer Zone, this modification is issued to insure the Government receives a reasonable credit.

This modification will result in the addition of one new item to the contract. The payment for this modification will be made in accordance with the following payment schedule:

Item No.	Description	<u>oty</u>	Unit	Unit <u>Price</u>	<u>Amount</u>
P00177	Credit for early removal of Buffer Zone	1	Job	Sum	(\$603,000.00)

Due to this modification, the total contract price as herein modified will be decreased by \$603,000.00.

The contract time will not be changed.

Page 2 of 2 Contract No. DACW69-88-C-0001 Modification A00059

Item No.	Description	Estimated Quantity	Unit	Unit Price	Amount
A00059-1	VE-Deletion of Piezometers in Structural Backfill	1	JOB	SUM	-\$16,050.00
A00059-2	VECP Incentive Adjustment to Contractor	1	JOB	SUM	\$8,827.50
Net Decrea	se to Contract Amount				-\$7,222.50

The total contract price is decreased by \$7,222.50 as a result of this modification. The total contract completion date remains unchanged by this modification.

This adjustment constitutes compensation in full on behalf of the contractor and its subcontractors and suppliers for all costs and markups directly and indirectly related thereto, including impact.

If the foregoing modification is acceptable, it is requested that you sign in block 15B, complete blocks 15A and 15C and return the original to this office.

Page 2 of 2 Contract No. DACW69-88-C-0001 Modification P00174

This change was referred to as Change "NN" for Modification P00137 and "HB" for Modification P00174.

The following work is included in this change:

- a. Additional rock excavation in areas of overbreak.
- b. Additional structural backfill in overbreak areas.
- c. Placement of concrete outside of neatline as required.
- d. Formwork in overbreak areas as required.

Since the contractor has declared negotiations at an impasse, this modification is issued to provide an equitable adjustment for the changed work.

This modification will result in the addition of 2 new items to the contract. The payment for this modification will be made in accordance wit the following payment schedule:

NO.	DESCRIPTION	OTY	UNIT	UNIT PRICE	AMOUNT
P00174-1	Deletion of Interim P'mnt	1	Job	Sum	(\$300,000.00)
P00174-2	Adjustment due Contractor	1	Job	Sum	\$286,693.06

Due to this modification, the total contract price as herein modified will be decreased by \$13,306.94

The contract time will not be changed.

It is considered that this adjustment constitutes compensation in full on behalf of the contractor and its subcontractors and suppliers for all costs and markup directly or indirectly attributable to the change order, including impacts, delays and interest, and for performance of the change within the time frame stated.

Re: Gallipolis Locks Replacement Contract #DACW69-88-C-0001

Serial Letter No. 21

November 10, 1987

Desident Engineer U.S. Army Corps of Engineers Euntington District P. O. Box 9 Apple Crove, WV 25502-0069

Dear Sir

Please define the limits of the five foot thick compacted impervious layer which is to be placed over the slurry cutoff wall. This impervious layer is only shown on the typical section of the slurry cutoff wall on drawing O-L26B-16/121.

Is this impervious layer required over the total length of the slurry wall? If so, what is the required elevation at the relocated access road and at the granular fill and structural backfill for the new access road? What is the required width of the impervious layer?

Very truly yours,

David E. Urban Project Manager

Attention: Mr. Ronald C. Harris

Subject: Extension of Slurry Cut-off Wall

Gentlemen:

GLR Constructors intends to utilize a slurry cutoff wall to expedite the excavation of material between the contract design slurry wall and the temporary Flatfoot Creek Extension.

Attached are six (6) copies of GLR Constructors drawing EX-3 which gives the location of the wall. The top of the wall will be at an approximate elevation 560 and will extend to rock.

If there are any questions please contact this office.

Sincerely,

David E. Urban Project Manager

Attention: Mr. Ronald C. Harris

Subject: Differing Site Conditions - Well Drilling

Gentlemen:

The enclosed letter from our dewatering subcontractor (Griffin) provides notification of a differing site condition as a result of encountering boulders during well drilling operations.

We request that the Contracting Officer take appropriate action pursuant to Article 46 of the Contract Clauses as soon as possible.

Thank you for your attention to this matter.

Sincerely,

. David E. Urban Project Manager

Enclosure

An Equal Opportunity Employer

February 24, 1988

GLH Constructors P.O. Box T Point Pleasant, Wv 25550

Attention: David Urban

Subject: Changes (1984 APR) FAR 52.243-4

Dear Mr. Urban:

In submitting our bid for dewatering we referred to the specifications reference (3.1 thru 3.2.4). The impression given was that the alluvium is "clay" underlain by "sand" and "sand and gravel."

Further, we were to anticipate "some gravel, coccles, and an occasional boulder." The specifications go on to say (and is underlined-3.2.2) that due to the split-spoon sampling method employed "gravel and copples" may exist. We note this paragraph cmits any reference to boulders.

Subsequently, in the drilling of wells #1 thru #4 we have in general encountered not only extensive layers +2' to 6' thick-of large cookles, but boulders as well at the 40'+ depth and again at 55' at each well location.

We now suspect this condition may continue throughout our phase of the work. This goes far beyond what we believe was what the owner anticipated and reflected in his specification.

To displace or remove these extensive deposits of cobbles and boulders has more than doubled our drilling time.

We believe the owner's <u>intent</u> was to anticipate only an occasional problem of this nature. Therefore, we are herewith submitting our request for a changed condition.

Please issue a change order to cover this extra time and cost.

Very Truly Yours,

Vince Cummings

Project Supervisor

Gentlemen:

As per your instuction the following hazard controls are now included in the hazard analysis for drilling and pipe laying.

Sincerely,

David E. Urban Project Manager

DEU:JJK:mm

Enclosures

March 3, 1988

From: Griffin Dewatering

The following is to be included in our hazard analysis:

Drilling. When moving the drill from one area to another, all tools and equipment shall be secure and the mast placed in a horizontal position. Particular care shall be taken when operating near power lines. All employees shall wear seat belts. Drill holes large enough to be a hazard shall be covered or guarded. When applying calcium hypochlorite, employee shall wear respirators. Men shall not be on a mast while the drill bit is in operation. Gloves shall be worn by operators, and caution shall be exercised around the augers in motion.

Pipe Laying. In removing 4" iron pipe from wells, remove one joint at a time. Do not lift long length of pipe into the air. No one shall be under a picked load. Cherry picker must be load tested, and have load chart posted in the operators cab. Must have one person designated as signal man. Employees shall avoid inhalation of fumes from pipe cement.

Subject: Additional Piezometers

Gentlemen:

Reference is made to Article 9.1(2), Specification Section 20 Control of Groundwater and Surface Water. Article 9.1(2) states that the groundwater table on each side of the slurry cutoff wall is to be measured by means of piezometers installed at the locations shown on the drawings.

The contract drawing showing the locations of piezometers (see Ø-L26B-16/121) does not show any piezometers on the outside of the slurry cutoff wall. Our subcontractor, Griffin Dewatering Inc., on their groundwater control plan (transmittal No. 2002) have proposed four (4) additional piezometers located on the outside of the slurry cutoff wall.

Should the Government wish to add the proposed piezometers, please be advised that GLR Constructors considers this a change to the Contract and shall expect an equitable adjustment to the Contract for any and all costs incurred due to this change. We request that we be furnished the Government's decision on the additional piezometers within ten (10) days from receipt of this letter.

Sincerely,

David E. Urban Project Manager

Subject: Slurry Wall Location Conflict

Change Item No. 3

Gentlemen:

Receipt is acknowledged of the Government Serial Letter Number 95, dated March 7, 1988. GLR Constructors does not agree with the Government's position on the subject issue.

The Contract clearly defines and shows the slurry cutoff walls extending from the natural ground elevation to the top of rock as previously stated in our Serial Letter No. 88-024. The impervious cap as shown in the Contract does not form an integral part of the slurry cutoff but is placed on top of the slurry wall to form a protective covering. The impervious cap as stated in the Government's response to question 35 of the Pre-Bid Conference is to be paid for under the bid item for "Compacted Impervious Materials" and is not incidental to the slurry wall construction.

GLR Constructors shall expect to be paid for the slurry trench cutoff wall as stated in Paragraphs 4.(5), 9.2 and 12 of Section 2E. The top of trench as shown on the contract drawings and as defined is the original ground elevation.

Preparatory Excavation Operation Hazard Analysis Plan

ICOS Corporation of America in setting up its hazard analysis plan will follow the U S Army Corps of Engineers Safety and Health Requirement Manual, EM385-1-1. Revised October 1984.

HAZARD

During the excavation of the slurry trench with the backhoe, the following hazards are presented. The trench excavation with bentonite slurry may have the possibility for personnel or machines to go into it.

HAZARD CONTROL

ICOS will mark and flag open areas of excavation. Also, the hazards will be discussed at safety meetings. To cross the excavation ICOS will use a bridge or personnel will cross behind the backhoe where no excavation has begun.

The bridge crossing the trench will have handrails.

All heavy equipment will be kept clear of the open trench edge.

When working near the lock wall esplanade or access road, special care will be exercised to insure the safety of the public and river traffic. A signal man will be used when necessary.

Patented Slurry Walls 🗆 Slurry Trenches 🗀 Onlling 🗀 Grouting 🗀 Jet Grouting 🖸 Bored Piles 🗀 Tieback Anchors 🗀 Turn-Key Fundations

HAZARD

The backhoe excavating poses two hazards to equipment and personnel.

- a) Swing of machine
- b) Moving backward

HAZARD

During the excavation of the slurry trench, cleaning of the excavation, removal of rock, and supplying Agitor backfill mixer with premixed backfill with the crawler cranes, the following hazards are presented.

- a) Swing of machine
- b) Moving backward
- c) Clamshell buckets

HAZARD CONTROL

ICCS, even though it is not required by the Operating Engineers
Union Agreement, will have an oiler whose job will be to insure clearances for safe excavation, in relation to personnel and property is maintained and normal maintenance to the machine.
ICOS will have a backup alarm. The alarm will work in either direction of travel automatically.
ICOS will instruct all personnel not to park any vehicles or equipment behind the backhoe during excavation periods.

HAZARD CONTROL

The soil specialist in the field or his/her assistants will set up the cranes in position and observe operation of, to insure personnel and property are protected from injury or damage from the swing of the machine or from the excavating buckets.

Personnel will not work or pass under clamshell buckets, picked loads, etc. The crane for backward movement will either turn so the operator has full view of where he/she is going or the soil specialist or his/her assistant will guide the crane back.

HAZARD

Agitor Backfill Mixer

- a) Various pinch points
- b) Elevated shell

HAZARD CONTROL

Before the personnel operate the Agitor mixer, they will be instructed as to its use and will read the operating manual.

Safety Decals.

(See attachment A)

HAZARD

Bulldozer premixing backfill and cleanup.

a) Movement in the field near cranes.

HAZARD

Backfilled slurry trench

- a) Personnel may walk into it
- Equipment may be driven into it.

HAZARD CONTROL

Operator will be instructed to watch cranes swing and stay clear where excavating buckets are in operation. Backup alarms will be used.

HAZARD CONTROL

Backfilled slurry trench will be flagged to alert all of its location and presence, until capped.

Capping on the completed portion of trench will be done in 500 + LF sections.

1. Forwarded for your review and guidance is the contractor's serial letter number 88-351. The contractor is requesting a variance in specification 2I-5 which requires a minimum distance of 400 feet be maintained between exploratory drilling and rock excavation. This variance only applies to specific holes in the outlet structure.

2. It is requested that you provide your response as soon as possible. This variance would allow the contractor to proceed with rock excavation for the river wall prior to removing the existing overburden at the outlet structure.

Resident Engineer U.S. Army Corps of Engineers Huntington District P.O. Box 9 Apple Grove, WV 25502-0009

Attention: Mr. Ronald C. Harris

Subject: Payment for Sill Excavation

Change Item No. 103

Gentlemen:

Reference is made to Progress Pay Estimate No. 35 dated March 25, 1989, Progress Pay Estimate No. 36 dated April 10, 1989, Specification Section 2F-6, Paragraph 7.3.2 - Sill Excavation and the statements made by our Mr. John Zito at a March 17, 1989 meeting.

GLR Constructors takes exception to the Government's position that sill excavation (Bid Item 14) is to only be paid below approximate elevation 495.0. The specialized blasting operation associated with sill excavation substantially differs than that for general rock excavation. The blasting operation for sill excavation begins at the top of rock elevation (approximate elevation 497.0) and therefore, payment should be made under Bid Item 14 for all excavation of rock at the sill locations.

In accordance with Contract Clause 44 - Disputes, the Government is hereby notified of the aforementioned demand for payment. As of April 10, 1989, payment in the amount of \$5,040.00 for Sill Excavation remains outstanding. We will continue to submit Progress Pay Estimates for all rock excavation at the sill locations under the Bid Item 14 unit price. Additionally, this letter will serve as notification of a change to the contract in accordance with Contract Clause 59.

P.O. Box 9
Apple Grove, WV 25502-0009

Attention: Mr. Ronald C. Harris

Subject: Preliminary Cleanup Change Item 101

Gentlemen:

Reference is made to GLR Constructors' Serial Letter No. 89-191, dated May 9, 1989, regarding preliminary cleanup of rock surfaces. The above referenced letter was written before any substantial amount of cleanup was completed.

Notwithstanding the Government's determinations that preliminary cleanup is unnecessary, a review of field operations and the contract shows that GLR Constructors is in fact, and of necessity, performing preliminary cleanup.

In support of the above, consideration should be given to the following:

- A) The obvious intent of preliminary cleanup is the removal of debris from the area above the top of the rock surface so that is also necessary so that areas of loose and drummy rock can be final cleanup operation.
- B) Final cleanup and foundation preparation, Paragraph 15.3 of section 2F, is the removal of loose and/or weathered rock etc. from the in place rock surface. It necessarily follows that any removals which are above the in place rock surface are not part of final cleanup.

- GLLR CONSTRUCTORS

GALLIPOLIS LOCKS REPLACEMENT

CONTRACT DACW69-88-C-0001

C) The bid quantity for preliminary cleanup is 78,000 sq. yd, whereas the bid quantity for final cleanup is 71,000 sq. yd. It is very obvious that the Government intended that all areas which required final cleanup would also require preliminary cleanup. GLR Constructors relied on this representation when submitting our bid proposal.

Our position on this matter was recently illustrated at monolith R-37. By Serial Letter No. 717, the Corps of Engineers directed that no preliminary cleanup was necessary. During the supposedly final cleanup, we were directed to perform further excavation.

In summary, it is our position that preliminary cleanup has been performed at all areas where final cleanup has been performed. These pay quantities will be requested for the pay period ending June 25, 1989 and in subsequent estimates as the work is performed.

Please contact us if you have any questions, comments or opposite opinions.

Sincerely,

David E. Urban Project Manager

Gentlemen:

Transmitted herewith is our documentation for Contract Progress Payment of Bid Item work performed through October 27, 1990.

The total amount due the Contractor is \$3,395,745.92.

The quantities in Bid Item 10 "Slurry Trench Cut-off Walls", Bid Item 269 "Portland Cement", Bid Item 270 "Pozzolan", and Bid Item 18 "Dental Treatment" have been revised to match the Government's quantities. In addition, all mass concrete quantities reflect "neat line" measurements. GLR Constructors reserves the right to pursue payment for any and all additional costs resulting from the excessive amount of incompetent rock encountered to date. These quantity reductions have been made solely to expedite the processing of this and future progress payments. In no way do these revisions signify acknowledgment of agreement with the Government's quantities completed to date.

Sincerely,

Robert L. Portley Project Manager

RECEIVED

Re: Lower Approach Wall Dewatering Gallipolis Lock & Dam Replacement

Gentlemen:

This letter will describe our dewatering plan for the above referenced project.

SCOPE

We plan on installing a series of deepwells from elevation 525'± to the top of rock (497'±). ..

We will use the jetting method for installation. The wells will be 12" in diameter, made of metal, with a sanitary cap installed for protection against high river elevation.

The pumps will be 440 volt, 3 phase, 15 horse power, with a bottom suction. They will have a four inch (4") discharge.

The wells on the river side will have their own separate discharge lines to the river. Wells on the land side will have a common discharge line (12" aluminum pipe) that will transport the groundwater to the river.

The starter boxes for the pumps will be placed on 4" X 4" poles near the cellular cofferdam. This will insure against damage when the river elevations rise. The starter boxes will be rainproof. Electric cable will run between each starter box and The cable will be a #10/4.

Transmittal No. 523B -Item 5 Response to Questions

- Encroachment of layout on the required D/S plug has been minimized by the deletion of cell 8 from this phase of the work. The encroachment on the D/S plug required for cell 7 is indicated on the layout drawing.
- 2) Open standpipe piezometers have been added per the Government's recommendation.
- 3) The general concept for the construction of cells 8 thru 19 was discussed at August 1, 1990 meeting. The detailed scheme for these cells will be submitted at a later date.
- 4) A well has been added at the downstream end of the dike.
- 5) Dikes shall be constructed of compacted impervious in accordance with Specification Section 2L.
- 6) Acknowledged.

TRANSMITTAL NO. 5238 CONTRACT NO. DACW69-88-C-CC01

COMMENT SHEET

The contractor's plan for the construction of cells 1 through 7 is approved subject to the following:

- Satisfactory performance must be achieved.
- b. It is assumed that the contractor has fulfilled his responsibility of coordinating the construction of cells 8 through 19 with this plan and that no problems exist. The contractor should procede to submit his plan for the construction of cells 8 through 19 as soon as possible.
- C. This work shall be performed in the October-November time frame as proposed by the contractor. While the months of October and November are historically low flow months, there is also a high potential for catastrophic flood events to occur in this time frame. It is assumed that the contractor has properly analyzed this risk and prepared his plan with the appropriate precautions. However, the government shall not be liable for any damages to work on the downstream cells due to a flood event.
- d. It is also assumed that the contractor has fully evaluated the effects of the encroachment on the downstream plug. Therefore, the contractor is assuming the additional risk of failure in the event of a catastrophic flood event and the government shall not be held liable should any damage occur due to the encroachment on the downstream plug.
- e. The contractor is reminded that the safety of the workplace is his responsiblity and as such he should be prepared to stop work on the downstream cells should failure of this dewatering and dike system appear imminent.

Attention: Mr. Ronald C. Harris

Subject: Contract Progress Payment No. 76

Payment Ending: December 29, 1990

Gentlemen:

Transmitted herewith is our documentation for Contract Progress Payment of Bid Item work performed through December 29, 1990.

The total amount due the Contractor is \$1,508,511.38.

The quantities in Bid Item 10 "Slurry Trench Cut-off Walls", Bid Item 269 "Portland Cement", Bid Item 270 "Pozzolan", and Bid Item 18 "Dental Treatment" have been revised to match the Government's quantities. addition, all mass concrete quantities reflect "neat line" measurements. GLR Constructors reserves the right to pursue payment for any and all additional costs resulting from the excessive amount of incompetent rock encountered to date. These quantity reductions have been made solely to expedite the processing of this and future progress payments. In no way do these revisions signify acknowledgment of agreement with the Government's quantities completed to date.

Sincerely,

Robert L. Portley Project Manager

Subject: October 1990 NAS Update Special Clause 18

Gentlemen:

Reference is made to the Government's Serial Letter No 1508 dated January 18, 1991, and to GLR Constructors Serial Letter No. 91-003 dated January 9, 1991. Pursuant to the Government's request, the following explanation is offered as to the incorporation of logic revisions to the October 1990 NAS Update.

The logic revisions for the activity for sill construction was revised for several reasons:

- 1) The activity for sill erection previously encompassed the construction of all miter gate sills, emergency gate sills, and maintenance bulkhead sills and provided virtually no parallel to related construction activities i.e. gate erection.
- The downstream sills were completed in May of 1990. The upstream sills have yet to begin and therefore a substantial lapse in the overall activity duration results in a false indication of actual construction duration.
- 3) The emergency gate sills have little correlation to the construction of the upstream miter gate and maintenance bulkhead sills. Because the network is limited in the number of schedule activities, only new activities were developed for the construction of the emergency gate sills since these sills involve the greatest amount of work. The upstream miter gate erection durations were extended to encompass the construction of the associated sills thereby avoiding additional activities. No schedule activities exist in reference to the maintenance bulkheads due to the restriction of schedule activities.

CONSTRUCTORS

CONTRACT DACW69-88-C-0001

Post Office Box T Point Pleasant, WV 25550 (304) 675-7050

The revisions to the miter gate erection logic were implemented solely to represent the most current planned erection sequence. The rection sequence is to erect the miter gates in the main look description. lock downstream, then the main lock upstream, then the auxiliary lock downstream and finally the auxiliary lock upstream.

Corrections to the October 1990 Report of Progress, which will be shown in the November Update, include:

- The scope of work under ANO 21201 "Cells D/S Guidewall Drive Sheets #1 to #8" was incorrectly changed to sheets #1 to #6, and shall be corrected to read "Cells D/S Guidewall Drive Sheets #1
- The scope of work under ANO 21202 "Cells D/S Guidewall Drive Sheets #9 to #14" was incorrectly changed to sheets #7 to #14, cheets #8 to #16"
- The scope of work under ANO 21204 "Cells D/S Guidewall Tremie Concrete #1 to #8" was incorrectly changed to cells #1 to #6, and shall be corrected to read "Cells D/S Guidewall Tremie Concrete
- The scope of work under ANO 21205 "Cells D/S Guidewall Tremie Concrete #9 to #14" was incorrectly changed to cells #7 to #14, and shall be corrected to read "Cells D/S Guidewall - Tremie

Additional title revisions are consequently necessary for ANO 21203 and ANO 21206 which will also be reflected in the November 1990 NAS

Sincerely,

Robert L. Portley Project Manager

Subject: Drilling of Weep Holes Change Item No. 272 (VECP)

Gentlemen:

Per Contract Specification Section 2V, weep holes are to be drilled with rotary type equipment but no core recovery is required. Additionally, the weep holes are to be thoroughly cleaned by flushing with water and compressed air and kept clean and plugged until the Contracting Officer directs the removal of the plugs.

GLR Constructors contends that, since the weep holes require cleaning after drilling, percussion in lieu of rotary type equipment can be utilized. Also, during operation of the locks, the weep holes will eventually become filled with silt, etc.

Therefore, we are pleased to submit our Value Engineering Change Proposal for the substitution of percussion in lieu of rotary type equipment for drilling of weep holes.

Our firm priced proposal is included as "Attachment I" which reflects a savings of \$9,853.00 to the Contract price.

We request that this proposal receive your favorable attention and acceptance as soon as possible since the weep hole drilling operation is scheduled to begin during early September 1991.

Attention: Mr. Ronald C. Harris

Subject: Contract Progress Payment No. 93
Payment Ending: September 14, 1991

Gentlemen:

Transmitted herewith is our documentation for Contract Progress Payment of Bid Item work performed through September 14, 1991.

The total amount due the Contractor is \$6,337,387.73

The quantities in Bid Item 10 "Slurry Trench Cut-off Walls", Bid Item 269 "Portland Cement", Bid Item 270 "Pozzolan", and Bid Item 18 "Dental Treatment" have been revised to match the Government's quantities. In addition, all mass concrete quantities reflect "neat line" measurements. GLR Constructors reserves the right to pursue payment for any and all additional costs resulting from the excessive amount of incompetent rock expedite the processing of this and future progress payments. In no way do these revisions signify acknowledgment of agreement with the Government's quantities completed to date.

Sincerely,

Robert L. Portley Project Manager

October 1, 1991

Resident Engineer U.S. Army Corps of Engineers Huntington District P.O. Box 9 Apple Grove, WV 25502-0009

Attention: Mr. Des Goyal

Subject: Core Drilling

Bid Item 31 A Through E Specification Section 2I

Gentlemen:

Reference is made to the above subject and specifically to your Serial Letter No. 1832, dated September 26, 1991.

Core sample photo for R59/1 was provided on Transmittal No. 2091, dated February 23, 1989.

Core sample photos labeled L24/1 were sent to you twice (Transmittal No. 2089, dated February 13, 1989 and Transmittal No. 2093, dated March 7, 1989). GLR Constructors is of the opinion that one of the above photos was mismarked and should be labeled L24/2.

If GLR Constructors can be of further assistance, please do not hesitate to contact the undersigned.

Sincerely,

Robert L. Portley Project Manager

Subject: Fill Weep Holes with Pea Gravel Change Item No. 316

Re: Government Serial Letter No. 1910, dated November 21, 1991

Gentlemen:

Per the above referenced letter the Government requested GLR Constructors to provide a cost proposal to incorporate the subject additional work into the Contract.

Pursuant to Contract Clause 59 - "Changes", GLR Constructors herewith proposes an increase to the contract price and a contract modification is requested to provide the following:

BID ITEM NUMBER	DESCRIPTION	QUANTITY	UNIT	PRICE	Mother	
New	Pea Gravel for Weep Holes	1	Job	LS	AMOUNT \$18,548.60	

This proposal is based solely on the usual cost elements such as labor, material and normal markups and does not include any amount for changes in sequence of work, delays, disruptions, rescheduling, extended overhead, acceleration and/or impact costs.

GALLIPOLIS LOCKS REPLACEMENT

CONTRACT DACW69-88-C-0001

We therefore, expressly reserve the right to make claim for any and all of the aforementioned exclusions and related items of costs prior to any final settlement of this contract.

Sincerely,

ge mason go

Construction of the New Gallipolis Locks
Contract No. DACW69-88-C-0001

G.L.R. Constructors
P.O. Box "T"
Point Pleasant, West Virginia 25550

Gentlemen:

This letter will confirm information verbally provided members of your staff on March 1, 1989.

As you are aware, various procedures have been utilized for presplitting along interior and exterior corners of the lockwalls. However, no method has been fully successful in leaving exterior rock corners intact.

It is the government's position that every possible effort must be utilized to keep exterior rock corners intact. Therefore, presplit holes may be drilled on a 45 degree line from exterior rock corners to a point that intersects the neat line dimension of the adjacent wider monolith. This procedure may be utilized to prevent propogation of the presplit across the exterior rock corner, when an offset of 4' or less exist between two adjacent monoliths in plan view. (See example #1, SK-Rock Excavation.) The 45 degree line used for presplitting in the above procedure will be the neat line dimension utilized for rock excavation and concrete payment.

When the offset dimension between adjacent monoliths exceeds 4 feet in plan view, the interior corner will be presplit to a point 4 feet from the exterior corner. The exterior corner may be line drilled to a point 4 feet in either direction of the exterior corner. The government will proceed to pay for the necessary line drilling of these corners as outlined in the contract for line drilling. (See ex. #2, SK-Rock-Excavation.)

In addition to the above procedures, it has been determined necessary to line drill all exterior rock corners adjacent to monoliths M-7, M-13, and M-29. The government will proceed to pay for the necessary line drilling of these corners as outlined in the contract for line drilling. (See ex. #3, SK-Rock Excavation.)

The government has also determined that for vertical steps of less than 2' between adjacent monoliths line drilling may be deleted. If line drilling is deleted for less than 2' steps down, rock must be excavated from the highest foundation along a 45 degree line extending to a point which intersects the designed elevation of the lower dimension utilized for rock excavation and concrete payment. (See ex. #4, Sk-Rock Excavation.)

The reinforcing steel shall be field adjusted to fit all cases in which the above alterations are utilized at no additional cost to the government.

Should you have any comments and/or concerns you may contact my office.

Sincerely,

Ronald C. Harris Authorized Representative Of Contracting Officer

CEORH-OC (CEORH-CD/15 May 89) (1180) SUBJECT: Payment for Sill Excavation, Construction of the New Gallipolis Locks, Contract No. DACW69-88-C-0001

TO: CEORH-CD

FROM: CEORH-OC

DATE: 14 July 1989 Williams/sda/5261

CMT 2

- 1. We have reviewed the attached package and GLR's claim relative to payment for sill excavation and opine as follows:
- 2. We concur that sill excavation is to be measured for payment purposes, as provided by Section 2F, paragraph 19.3.3, based on the volume of material excavated in a sill excavation area using the sill excavation techniques in paragraph 12.6 (primarily), and not based on the location of the excavation and/or the type of blasting only.
- 3. It is our understanding that GLR used the techniques for excavating material classified as "Rock Excavation" to excavate the material in question (i.e., the top portion of rock in the sill areas) as opposed to using sill excavation techniques and was paid accordingly under Bid Item No. 12, "Rock Excavation". We think such was proper.

FROM CEORH-CD

CMT 1 15 MAY 89 CMT 2

GREENFIELD/jks/5727 Forwarded is a claim relative to the measurement and payment for Bid Item No. 14, Sill Excavation.

- 2. Reference Contract Specifications Section 2F "Excavation" paragraph 2.3.2; 12.6 and 19.3.3 all "Sill Excavation."
- The issue centers on the limits for measurement for the bid item. Rock excavation is paid under three different items - "Rock Excavation", "Sill Excavation", and "Buffer Zone Excavation". These three items were set up to protect rock faces to be left in place. Each have different requirements and, therefore, different costs. For instance, sill excavation would have large pieces of rock left after blasting which would require additional mechanical breaking before they could be removed. The regular rock excavation would not require this extra effort. Normally, the measurement and the payment item would define these different types by location. However, in this contract they are defined by excavation procedure. The problem is that the upper portion of rock in the gate sill location was not removed by the gate sill procedure. Instead, the Contractor was able to remove it with the "Rock Excavation" procedure. Contractor claims the sill payment should be used since it was in the sill area. The Government thinks it should be the rock excavation item because of the method. The Contractor contends that measurement should include all areas of the sill excavation from elevation 497 down to the foundation bottom, 484 or so. The Government measurements include only the volume as defined by the specialized procedures to protect the rock surface that will remain in place. (See paragraph 12.6 Sill Excavation)
- The contractor attempts to reinforce his position by reviewing the Governemnt estimate calculations showing the quantity approximates the estimated quantity. He does this by utilizing a top elevation of 497 as did the Government in their estimate.
- The Resident Engineer and staff have taken the position that payment for "Sill Excavation" should only include that rock which is excavated by the method described in subparagraph 12.6 and any rock in the sill area excavated by other means should be paid for under bid Item No. 12 "Rock Excavation." The contractor did line drill the entire sill from the top of rock elevation 497 however, his rock operations removed rock from elevation 497 to 495 and also a portion of the sill area down to approximate elevation 488+. His contention is that he should be paid for any rock between the line drilled surfaces upstream and downstream and the side buffer zones with the top of rock at elevation 497 thus ignoring the shown top of rock at 495±. (See drawing 0-126B-20/135 and 136 for a better understanding)

CEORD-ED-G

MEMORANDUM FOR RECORD

SUBJECT: Site Visit to Gallipolis Lock Construction Project

1. <u>Purpose</u>: The purpose was to inspect rock excavation and treatment for construction of the Gallipolis Locks and to provide an opportunity for professional development for geologists and geotechnical engineers from ORD districts.

12 July 1989

- 2. Place and Date: The visit took place at the Gallipolis Locks and Dam, WV on 21 June 1989.
- Attendees: See attached list.
- 4. Background: This trip was in response to my request to Messrs. Steve Hornbeck, CEORH-ED-G and Pat Oshel, CEORH-CD for a Gallipolis site visit for geologists and geotechnical engineers from Louisville, Nashville and Pittsburgh Districts. Because of the diminishing number of large civil works projects throughout the Corps, many geotechnical professionals will be denied an opportunity to see and gain experience from a project under construction. Inspection of a project undergoing foundation development and treatment would provide valuable information and experience to this end. With concurrence and strong support of their superiors, Messrs. Hornbeck and Oshel made all necessary arrangements for the site visit.
- 5. Observations: An excellent project information briefing was presented by Messrs. Hornbeck, Oshel and David Nugen, Gallipolis Project Geologist. Mr. Hornbeck covered project deign emphasizing geotechnical aspects. Mr. Nugen covered construction details, with emphasis on geotechnical.

Following the briefing, Mr. Nugen led the site inspection, beginning with a vehicle tour of overall construction operations and concluding with a walking inspection of rock foundation development and treatment. As Mr. Hornbeck noted in his briefing, sandstone is predominant in the downstream end of the project, siltstone is predominant in the middle portion and weaker less competent claystone is the primary foundation rock in the upstream end. Rock excavation and foundation development are progressing well with the contractor having made the first concrete placement the previous week. (Full concrete production should be starting in a few weeks.)

Excavation of rock is continuing from general top of rock elevation 497 to general foundation elevation 484 with elevation differences for individual monoliths. Excavation of final faces is accomplished using a variety of blasting techniques including presplitting, line drilling and buffer zone blasting. Difficulties holding exterior corners are continuing as noted in a previous site visit report (CEORD-ED-G MFR, subject: Site Visit to Gallipolis Lock Construction Project, dated 28 March 1989). The upper sandstone between the downstream culvert crossover excavation had been damaged and portions of this rock will have to be removed. Air and water sensitive claystone are protected by application of an emulsion binder which forms a surface seal. (No binder was applied during the visit.)

CEORD-ED-G

SUBJECT: Site Visit to Gallipolis Lock Construction Project

12 July 1989

- Discussion: Following the inspection, we returned to the Resident Office and I met briefly with Messrs. Oshel and Nugen. I suggested that scaling of loose rock should be performed at a number of places along the excavation and minor touch-up of claystone with Aerospray Binder was necessary. Mr. Nugen agreed noting that each of these operations must be performed continually.
- Conclusions: The project looks very good. Overall rock excavation and treatment are proceeding as designed. The visitors from the other three districts were very complimentary of project and personnel, especially Messrs. Hurthest and Nugen. Huntington District, and particularly personnel involved with the site visit, should be commended for hosting the visit and for sharing

Construction Division Gallipolis Resident Office

SUBJECT: Preliminary Cleanup of Monoliths

Construction of the New Gallipolis Locks

Communication of the second of

Contract No. DACW69-88-C-0001

G.L.R. Constructors P.O. Box "T" Point Pleasant, West Virginia 25550

Gentlemen:

Reference is made to your serial letter number 89-191 concerning the subject matter.

The interpretation presented in my serial letter number 834 should clarify my position on preliminary and final cleanup. I stated that preliminary cleanup will be utilized for foundation inspections and mapping prior to final cleanup. Therefore, preliminary cleanups will not be eliminated as originally thought. I continue to disagree with your opinion that by eliminating the work under bid item 16, Preliminary Cleanup, would increase your cost under bid item 17, Final Cleanup. However, since preliminary cleanup will not be eliminated, your notice of a constructive change is no longer considered applicable.

Should you have any questions and/or concerns you may contact this office.

Sincerely,

Ronald C. Harris Authorized Representative Of Contracting Officer

SUBJECT: Preliminary Cleanup R-37 thru R-47 and M-15

thru M-25

Construction of the New Gallipolis Locks

Contract No. DACW69-88-C-0001

G.L.R. Constructors P.O. Box "T" Point Pleasant, West Virginia 25550

Gentlemen:

Reference is made to Section 2F, Paragraph 15.2 of the Specifications.

This letter will confirm information provided your Mr. John Zito on April 10, 1989, by Mr. Pat Morgan of my office.

It has been determined that no preliminary cleanup is necessary at this time for monoliths R-37 thru R-47 and M-15 thru M-25. You may proceed with a temporary earth cover for these monoliths.

It is requested that you notify the government as foundations are exposed, so as to allow for preliminary cleanup and the installation of the temporary earth cover within the seven (7) days specified in Paragraph 17.2 of Section 2F.

Should you have any comments and/or concerns you may contact my office.

Sincerely,

Ronald C. Harris Authorized Representative Of Contracting Officer

FINDINGS OF FACT

- 1. On October 23, 1987, the United States of America, represented by Colonel Robert D. Brown III and S.J. Groves and Sons Company (Sponsor); Guy F. Atkinson Construction Company; Dillingham Construction Company, N.A., Inc.; Harbert International; doing business as G.L.R. Constructors (hereinafter referred to as GLR) entered into Contract No. DACW69-88-C-0001 (Tab 4). Such construction contract was entered into for the estimated amount of \$217,622,583.00 and is entitled, "Construction of Locks in Canal, Gallipolis Locks and Dam, Ohio River (West Virginia)."
- 2. The contract requires completion within 1680 calendar days after the date of the Notice to Proceed. The Notice to Proceed letter was acknowledged on November 20, 1987 (Tab 5).
- 3. Pertinent clauses relative to this dispute are:
 - A. Contract Clause 44 entitled "DISPUTES".
 - B. Contract Clause 59 entitled "CHANGES".
- C. Contract Clause 72 entitled "CONTRACT PRICES BIDDING SCHEDULES".
 - D. Technical Contract requirements, Division 2, Site Work, Section 2F Excavation.
 - 4. Relevant contract drawings are:
 - A. 0-L26-20/135
 - B. 0-L26-28/136
 - 5. Progress Payment Estimates:
 - A. No. 35, dated March 25, 1989
 - B. No. 36, dated April 10, 1989
- 6. By letter, dated April 24, 1989, your serial letter No. 89-170, you submitted your claim for additional payment for sill excavation in the amount of \$5040.00. You further state that you will continue to submit Progress Payment Estimates for all rock excavation at the sill locations under the Bid Item 14 unit price.

-3-

ANALYSIS

It is the position of the Government that Sill Excavation is to be measured for payment purposes, as provided by Section 2F paragraph 19.3.3, that is, based on the volume of material excavated, in a sill excavation area, using the sill excavation techniques, and not based on the location of the excavation only.

The contract is very specific as to how sill excavation is to be measured for payment purposes. It states in Section 2F, paragraph 19.3.3 sill Excavation: "Sill excavation will be measured for payment based on the volume of material excavated using sill excavation techniques previously specified...."

The specialized techniques for sill excavation are provided by paragraph 12.6 of Section 2F:

Sill Excavation. Excavation of those areas on or against which the concrete for the various gate sills will be placed will require specialized procedures to protect the rock that will remain in place. Sill excavation shall consist of light blasting supplemented by mechanical methods so that fragmentation will not be the controlling factor in the design of the blast. The blast shall be designed so that the rock is broken but the fragment size is such that removal by conventional excavating equipment is not possible without the use of supplementary mechanical methods such as hydraulic rock splitters, or boom-mounted demolition hammers such as those... Additional requirements for sill excavation are contained in paragraphs, Line Drilling, and Buffer Zone Excavation.

Only rock excavation using sill excavation techniques are to be measured and paid for under Bid Item 14, "Excavation, sill". You elected not to use these specialized procedures to remove the top portion of rock from the sill areas. You excavated the quantity of material in question using the continuous systematic blasting, ripping, or wedging techniques for excavating material classified as "Excavation, Rock", and were paid for accordingly under Bid Item No. 12, "Excavation, Rock".

-4-

DECISION

Pursuant to the foregoing discussion, I find no basis for your claim for additional costs and, therefore, deny the same. This is my final decision as Contracting Officer. This decision may be appealed to the Corps of Engineers Board of Contract Appeals. Should you decide to make such an appeal, you must mail or otherwise furnish written notice thereof to the Corps of Engineers Board of Contract Appeals, Ruth Price, Recorder, Washington, D.C. 20314, within 90 days from the date you receive this decision. A copy of the notice shall be furnished to the Contracting Officer from whose decision the appeal is taken. The notice shall indicate that an appeal is intended, shall reference this decision, and identify the contract by number. For appeals under the Disputes Clause, you may, solely at your election, proceed under the Board of Contract Appeals small claims procedure for claims \$10.000 or less or the accelerated procedure for claims \$50,000 or less. In lieu of appealing to the Corps of Engineers Board of Contract Appeals, you may bring an action directly in the U.S. Claims Court within 12 months of the date you receive this decision.

The rules of the Corps of Engineers Board of Contract Appeals will be made available to you by the Recorder of the Board.

Sincerely,

Thomas E. Farewell Colonel, Corps of Engineers Contracting Officer

CERTIFIED MAIL - RETURN RECEIPT REQUESTED

(COGLSEX1) August 1, 1989

Construction Division Contract Administration Branch

SUBJECT: Contracting Officer's Decision - Payment for Sill Excavation (Rock) under Bid Item No. 14. Contract No. DACW69-88-C-0001, Construction of Locks in Canal, Gallipolis Locks and Dam, Ohio River (West Virginia).

GLR Constructors Post Office Box T Point Pleasant, West Virginia 25550

Gentlemen:

By letter dated April 24, 1989, your serial letter number 89-170 (Tab 3), you submitted a claim in the amount of \$5,040.00 and requested a Contracting Officer's decision regarding the Government's position of making payment for Sill Excavation under Bid Item No. 14 from below approximate elevation 495.0 in lieu of from elevation 497.0, the approximate top of rock.

Tab numbers mentioned herein refer to the location of the document in the potential appeal file.

SUMMARY OF CLAIM

You maintain that specialized blasting operations associated with sill excavation substantially differs from that for general excavation. You maintain that the blasting operations for Sill Excavation begins at the top of rock elevation (approximate elevation 497.0) and therefore, payment should be made under Bid Item 14 for all excavation of rock at the sill locations. You take exception to the alleged Government's position that sill excavation (Bid Item 14) is only to be paid for below approximate elevation 495.0.

Dental Treatment

Construction of the New Callipolis Locks Contract No. DACW69-88-C-0001

DATE

CEORH-CD

FROM CEORH-CD-GAL

15 November 1989 CMT1 MORGAN/cdh/576-9901

- Reference is made to Section 2F, Paragraph 16, 16.1, 16.2, and 19.7 of the subject contract.
- 2. The contractor has brought to my attention that he does not agree with the criteria being utilized for measurement of dental treatment. To date the government has paid for dental treatment based on the volume of concrete necessary to fill voids, crevices, depressions, joints and etc., to an elevation so that three (3) inch mass concrete can be satisfactorily placed without vibration problems and concerns for voids. The contractor has stated that this quantity is insufficient to adequately address the cost associated with the item. In several instances, the quantity of concrete placed back to a satisfactory foundation is only a portion of the excavation required to remove unsound and drummy rock. This required excavation is considered by the contractor to be a major portion of the cost of dental treatment and is not covered when payment is based on the quantity of concrete placed
- The government's criteria for payment of dental treatment has been predicated on the interpretation of dental treatment requirements as well as preliminary and final cleanup. Any excavation of depressions, crevices, and etc., not replaced with dental concrete has been considered
- 4. It is requested that guidance be provided as to the intended criteria to be used for measurement of dental treatment. Should the measurement be based on the quantity of dental concrete placed to achieve a satisfactory foundation for additional mass concrete, or should the amount of excavation in total preparation for dental treatment be the
- 5. It is requested that guidance be provided by 4 December 1989, as this

RESIDENT ENGINEER: PAT MONGAN DATE: 1/12/9/

TECHNICAL PROPOSAL:

ETI/Explosives, Inc. propose to furnish the explosives and blaster to remove the gantry rail footers. Drilling will be performed by GLR Constructors.

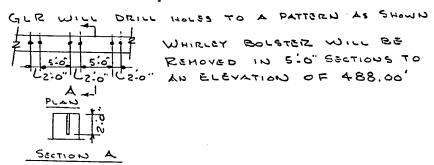

Based on desired fragmentation size and the depth of the footer, ETI will design and layout the the drill pattern for GLR. To insure good explosive distribution and blast control, drill hole size should be between 1-3/8 to 1-3/4 inches in diameter. Water Gel explosive 1-1/4 x & is proposed. This product is selected because of consistency and water resistance which will insure both safety and control. Initiation will be with electric detonators (unless otherwise required by GLR or the Corps of Engineers). In conjunction with a sequential timer, detonation delay can be adjusted to suit the pattern design and vibration restraints. Stemming of the blast holes will be done with clay. This reduces potential shrapnel, if the blast hole should rifle due to undetected confinement.

Based on general blast criteria and the confinement nature of the footer, the vibration limitation of 4 inches per second proposed by the Corps of Engineers, should not present a problem. Using the following vibration blast formula extracted from the "DuPont Blasters' Handbook", page 426, expected vibration clevels are well withing the excepted limits.

PPV=160 (Dist/Wt1/2) -1.6

Using a distance of 20 feet and a charge weight of 1 pound, the expected peak particle velocity is 1.33 inches per second. (Note: A 1-1/4 x 8 catridge is about 1/2 pound of explosive) The use of the sequential timer can also keep blast frequencies high, further reducing the risk of potentential vibration damage. A seismograph will be used to insure compliance with the Corps of Engineers limitations.

For estimating purposes, assuming total fragmentation of the footer, use a centerline drill pattern on 2 foot centers to a depth withing 3 inches of bottom of the footer. Wider spacings can be used if fragmentation can be courser or footer is to be removed in block sections. Explosives consumption is 1/2 lb per three feet drill hole and one detonator per 1/2 pound of explosive. Estimated time to load is one day.

Construction Division
Gallipolis Resident Office

SUBJECT: Rock Overbreak, Construction of the New Gallipolis Locks, Contract No. DACW69-88-C-0001

G.L.R. Constructors P.O. Box "T" Point Pleasant, West Virginia 25550

Gentlemen:

The following procedures shall be utilized in areas where the vertical rock faces have overbroke.

Neat line shall be formed as soon as practical in areas of overbreak faces for monoliths. No concrete shall be placed more than one foot outside neat line as a continuous part of the designed monolith (i.e. areas greater than 1' must be formed).

The voids created by forming of neat line in areas of overbreak do not need backfill except as follows:

- Overbreak areas for monoliths L-16 thru L-25 (Lock side) must be cleaned and backfilled with concrete.
- Overbreak areas for monoliths M-29 thru M-37 (Main Lock Side) must be cleaned and backfilled with concrete.
- Overbreak areas for R-28 thru R-37, R-52 thru R-64 and R-78 thru R-92 on the lock side shall be cleaned and filled with concrete. $\frac{1}{2}$
- All sills on both sides and all outside bends in conduits shall be cleaned and backfilled with concrete.
 - All areas within the chambers, where overbreak has occurred and no concrete is replaced shall be graded to prevent safety hazards during dewatered conditions.

G. L. Fl.
